In this line of thought and based in research on the formation of European identities in a globalizing world, the intriguing concept of a 'European mental space' has been developed (Schütze and Schröder-Wildhagen, 2012). The narrative interviews conducted with several groups who systematically experienced international and transnational encounters within and outside of Europe over a longer period of time, revealed that one cannot assume a European identity comparable to national or other collective identities, as a specific form of 'we-relation' in the sense of Alfred Schütz. Instead, a 'European mental space' is developing as a frame of reference in which comparisons of lifestyles based in experiences is possible; biographical opportunities as well as obstacles in mutual recognition of competences are becoming visible; and arenas for younger generations to work through historically burdened relations is evolving – to name just a few relevant aspects of this concept. A presently developing European mental space might serve in the future as basis to build more coherent 'we-relations,' which are only effective if rooted in common experiences, mutual comparison, critique, and recognition. Even though national identities still prevail, in the frame of a European mental space they become more liberal and loose.

Migration and Transnational Biographies

Research on ethnicity and collective identities is, not surprisingly, closely connected with investigations of the biographical meaning of migration processes. Migration research in sociology traditionally has been an area of quantitative research focusing on the flows of migration, on push and pull factors, on structural conflicts and changes in immigrant societies, and on social stratification connected mainly to work migration, etc. The experience of migrants and their patterns of action only recently have become a broader topic in scholarly discussion, particularly in connection with the criticism on the 'methodological nationalism' inherent in macro-sociological perspectives in former mainstream migration research. There have been pioneering and innovative conceptual contributions from biographical research to this shift in migration research (Apitzsch and Siouti, 2007; Breckner, 2007; Lutz, 1993).

One of the main insights has been that the considerable family- and ethnic milieu-orientation in migrant communities can be a forward-oriented strategy supporting the second and third generation to socially advance in the immigrant society and cope with exclusion, rather than a backward link to the society from where the migrants came. This insight resulted from in-depth biographical studies and led to criticism of concepts of modernization which were widely applied in migration research mostly from a macro-sociological perspective. The latter presupposes that the attitudes, especially of working migrants, as shown in religious habits and traditional family structures, are characterized by backward traditionality and a gap in modernization compared to secularized life worlds, and thus were the main obstacles in a normative perspective favoring assimilation as solution to social tensions. In contrast, biographical as well as ethnographic research, which included families and members of different generations, revealed that seemingly obvious (because visible) signs of 'premodern backwardness,' like symbols of religiosity and emblems of traditionality, are due to reflexive processes in dealing with a current social situation rather than reminiscences of a past that has to be overcome in a modern society in order to adapt. A more adequate and differentiated understanding of gender roles, ethnic communities, and religiosity could evolve through the complex interplay between the knowledge developed in one society orienting everyday life in the perspective of the whole lifespan and greater generational

transmission, with that developed newly in another society and milieu from the position of 'foreigner' or 'stranger' (Apitzsch and Kontos, 2008; Inowlocki, 2006).

In this line of thought the general image of 'migrants' is changing. Within the well-known concept of Robert Parks 'marginal man' as a prototype of the migrant, the experience of migration necessarily seems to create personal disorder. Looking at migration experiences and how they are situated in biographies, one can see that personal crises and trajectories of suffering triggered by migration can, but do not necessarily happen. Experiences of crises and strangeness are not caused by the fact of migration itself, but by its being embedded in an overall biographical construct (Riemann, 2003), by the shape of the border which has been crossed in respect of the possibility of return, by the conditions of immigration, and not least by the historical relations between the respective societies of departure and arrival, which have the potential to sharply shape experiences of discrimination or acceptance of migrants. The latter can be structured by relations built on cooperation versus hierarchical subordination, domination, or even by hostility, with a broad range in between, including ambivalence on a collective level (Breckner, 2007; Waniek, 2012).

Altogether, with a biographical approach specific aspects and dimensions of the complex field of migration can be grasped. Migration can be reconstructed as a process with an open beginning and an open end. Here the concrete social contexts in which migration is embedded and experienced by those involved become visible. The perspective of migrants which develops from their experiences in the contexts of both departure and arrival is part of the subject matter. The extent to which migration implies or requires changes of orientation and action patterns and the extent to which it allows or supports the continuation of orientation is revealed. Furthermore, with a biographical perspective addressing an entire lifetime and the interrelations between different life spheres, it can be shown how experiences of migration and its trajectories are connected with the dynamics and trajectories in other life spheres (e.g., the professional or the family sphere); how migration experiences interact with specific life phases, careers, or status passages; how the meaning of migration can change over the course of time and in relation to different biographical and societal contexts; and how members of the same immigrant community experience migration differently. Immigrant communities no longer appear as homogeneous or even subject to monolithic 'otherness,' but can be seen as a space for interactive negotiation between experiences connected to life in the societies which were left and the current position of being a migrant in a receiving society (Breckner, 2007: 118).

Finally, the contributions from biographical research to the broad discussion of different concepts of transnationality are remarkable and outstanding. I can outline here just a few. Biographical and anthropological research in Russian–Israeli and Russian–Jewish–German communities on the meaning of food and its transformation in a new societal context, while it still is perceived and practically kept as a strong link to the society and culture left behind, shows how transnationality is literally and materially created by food as an important means for creating family and community bonds (Bernstein, 2010). Other research focuses on how the second generation of work migrants in Germany do not completely transcend their national belongings, but negotiate them biographically to serve as enlarged opportunity e.g., for having educational careers in two different countries trying to overcome the obstacles of each. However, the challenges in transnational lives become apparent when opportunities are not backed by the still-prevailing institutional structures organized within the frame of nation states, as e.g., the social security and educational systems even within Europe, Bologna notwithstanding. As a result from this research, sensitive concepts of transnationality are claimed (Siouti and Ruokonen-Engler, 2014).

Gender and Intersectionality

Following up from the research on transnational migration, investigations of its impact on gendered experiences, biographies, and the gender order in general, are major contributions to this broad field of scholarly research (Apitzsch, 2012a; Lutz, 2011). The life world and biographical paths of the 'new maids' in Germany (mostly women working in private households, in general without work permission or social security arrangements, coming mainly from Poland, the Ukraine, and other Eastern European Countries), has been examined (Lutz, 2011). This research gives close insights into a field which publicly is barely visible; and it shows how global shifts in the distribution of work concretely take place and how their consequences are experienced by those involved on the side of the employers as well as by the jobholders in an unregulated transnational job market. It becomes apparent, that the concept of 'nuclear family' as one based in face-to-face close relationships is changing, because mothers work abroad leaving their children with grandparents or other members of a wider family, and keep in touch with them almost exclusively by phone or Skype, bridging the long distances and periods of absence.

In connection with recent feminist discourses, biographical research in this area expands theoretically as well as methodologically by elaborating 'critical sociological theory' and contributing to its development with concepts of intersectionality (Lutz et al., 2011; Davis, 2014a). These are based on empirically consolidated findings about the way in which gendered experiences and situations concretely connect with class positions and ethnic belonging or ascription in biographical trajectories (Lutz and Davis, 2009). Approached from a biographical angle, gender, class, race, and ethnicity are not perceived just as categories which have to be related in an abstract theoretical model, but as intertwined experiences and situations in which one dimension can get more relevant as another, or drops to the background at all, only to come to the fore in another biographical context, period of time, or social space. The challenge present in almost all biographical research, to precisely reconstruct the connection between personal experiences, orientations, and action with global societal transformation, undermining the distinction between micro-and macro-approaches in sociology, is explicitly addressed in this area. How social inequality among women develops on a global scale and at the same time is negotiated in concrete interactive settings, how gender roles in everyday life practices and their generational transmission

are negotiated, and how an increasingly global economy touches and transforms local gender arrangements are core topics to understand how structural global changes go along with the transformation of locally bound social settings.

Social Exclusion and Inclusion

Finally, issues of social exclusion and inclusion, social inequality, policy, and social work constitute other areas of research in which biography strongly matters. Practitioners in these areas always have been well aware of the fact that biographical processes and trajectories can be deeply shaped by experiences of discrimination and even exclusion resulting from an ascribed or felt belonging to a social group or category. Likewise, to find ways to overcome critical life situations, the biographical as well as collective resources have to be taken into account. Research on how to deal with crises and risks by understanding the individual perspective of those affected without individualizing them has been at the core of various research projects (Chamberlayne et al., 2002; Santos, 2010). Additionally, the consequences of professional intervention on the lives of subjects are investigated in order to develop, together with practitioners in social work, a self-reflexive attitude which is crucial, also as part of professional formation (Dausien et al., 2008; Siouti and Ruokonen-Engler, 2014). To understand oneself to a certain extent is regarded as necessary for understanding and helping others to cope with difficult situations. This area is also connected with educational sciences where biographical approaches are even more widespread than in sociology. Especially questions concerning education and lifelong learning have been at the center of interest over a long period of time (Alheit and Dausien, 2007; Olesen, 2012).

Conclusion

In a globalizing world, different concepts of biography and life story rooted in different societal organizations and cultural traditions of narratives appear and start to interact. The inter- and transcultural encounters of different social concepts on the organization of life experiences in a meaningful and orienting frame will bring about changes in the concept of biography and its narrative patterns as understood and examined in so-called western societies. In what way the social concept of 'biography' will travel or disseminate globally in the future, will remain an intriguing project for scholars to examine.

In conclusion, 'biography' and 'society' still matter and will matter in the future. The further development of methodologies and methods has been a relevant field of biographical research integrating narrative, ethnographic, and discourse approaches. Innovative potential for further development of methodologies and methods has evolved by addressing the body and emotions as a relevant part of social life that is closely related to biography, and by taking in the visual dimension of constructing biographies together with narratives in the context of changing media technologies.

Furthermore, biographical research matters because of its contributions in analyzing and understanding major issues in changing societies. Biographical approaches have the potential to concretely show how societal upheaval, shifts in social systems, and in general social structures affect the lives of those involved, and how actors contribute to shaping the social contexts they are living in. Especially the aftermath of social crises, historical shifts, war, and genocidal atrocities lived and transmitted through different generations become visible through reconstructing biographies and family histories by eliciting and analytically understanding their narratives. This applies also to understanding the complexity of migration processes. Viewpoints on specific groups of migrants in public discourse, which often bear discriminatory clichés and prejudices, are confronted with the perspectives of those who are ascriptively ethnicized. By means of biographical approaches, a more sophisticated picture of the aspirations, habits, orientations, and prospects of individuals who are part of different ethnic or religious communities and negotiate different expectations, belongings, rules, and knowledge in organizing everyday life, can evolve.

How will these areas develop in the future? Given the situation of an increased visibility of an unequal global and local distribution of material resources, and of a multitude of separations and conflicts between different groups along class, gender, and ethnic lines, the search for new concepts of social inclusion will become essential and indispensable. Biographical research might focus more on these vital issues showing how ordinary people develop strategies to deal with social conflicts and inequality, and how, through institutional settings, they can be supported in their attempts to construct peaceful lives in the diversity of social contexts we all are involved in. The examination of passion as a strong feeling and its biographical power might expand to, and connect with, the political field thus showing that strong emotions like passion are a driving force, in positive as well as destructive ways, in the social construction of biographies. Another topic on which one can expect further biographical research, is the dynamic change in media technologies and their impact on the processes of constructing biographies by different means of communication. Conceptional considerations of these processes have just started. These new directions ensure that biographical research will continue to be a success story.

Abstract

This article defines the historical biography as encompassing both a reconstruction of a human life and a representation of a human individual. It shows that the historical biography is a genre that verges on a series of genres and disciplines. The history of the historical biography reaches from antiquity to present days, and the genre is characterized by variety and diversity, both in historical outlook, media, and methodology, and in a cornucopia of categories and forms. Different aims, archetypes, and methodologies of the historical biography have developed the genre into a prism for a multitude of preoccupations, until 'the biographical turn' in history during the first decade of the 2000s augured the genre of the historical biography as an interdisciplinary analytic field in its own right, placed in a battlefield of multifarious narrative forms.

Definition

Historical biography (from the Greek *historia*: inquiry, knowledge; *bios*: life; and *grafein*: writing) is a reconstruction of a human life and a representation of a historical individual.

Thus, the notion of biography encompasses more than a pure life depiction. It encompasses the events of a life, the narrative of a life, and the interpretation of its characteristics. The historical biography represents one of many ways of telling history. Traditionally, biography places the individual at the center of the narrative, instead of larger analysis of dynamics, structures, and events. As such, biography has been a controversial genre within the scholarly writing of history for centuries.

The historical biography is a genre characterized by variety and diversity, both in historical outlook, media, and methodology, and in a cornucopia of categories and forms. In terms of genre, historical biography verges on autobiography, literary biography, the traditional tale, the life story, and the biographical novel. In specialist professional terms, the historical biography relates to psychology, sociology, anthropology, history, and literature. In terms of protagonist, the historical biography is open to everyone and anyone, statesmen and farmers, generals and artists, philosophers and scientists, heroes and villains, women and men. As regards time scale, historical biography has existed since antiquity and up to the present. All this makes it an extremely complex and deeply fascinating genre. In present times, the historical biography is a multimedia phenomenon from the highest academic publications in different disciplines to the popular journalist biography and the electronic life stories of the entertainment industry. It diverges from fiction, but in its narrative form it shares similarities with the modern novel, which has long since broken with linear narrative in recognition that the passage of real life is fragmented.

2000 Years of the Historical Biography

Since antiquity, Western historical biography has been regarded as a branch of historiography and has developed from being an ethical-humanistic genre to being a genre consisting of various methodologies, forms, and styles within twenty-first-century specialized scholarship. As a genre, biography in the West is considered to have been established by the Greek Plutarch (AD 45–120), who published the comparative lives of Greek and Roman statesmen in *Bioi Parallelloi* (AD 125). This work, together with Tacitus' *De vita Agricolae* (AD 98), Diogenes Laërtius' biographies of Greek philosophers (AD third century), and Suetonius' *De Vita Caesarum* (AD 121), characterized what has been called the classical Hellenistic biography, built upon the fundamental principles of ethics: the central figures were either commended for having fulfilled their duty or censured for falling into the trap of ambition or arrogance. The aim was didactic, inspiring the general audience to become ethical acting subjects. Also the Christian gospels of the New Testament are seen as ideal biographies of antiquity. The classical biography type was maintained throughout the Middle Ages. A sidelong consideration must here be given to China's great historian Sima Qian, who very early in history developed a biographical form that belongs to a much later Western epoch: *Shiji* (Sima Qian, 145–185 BC). This work contains biographies, not just of eminent statesmen and soldiers, but also of individuals such as fortune tellers, courtiers, and murderers. A modern approach, in present Western terms, was demonstrated by Sima Qian's contemporary, the poet and literary historian Liu Xiang, whose work *Lienü zhuan* (78–79 BC) shows that female personalities in China were already at this stage considered worthy of biographical studies.

The Greek-Roman golden age of biography vanished with its empires, and in accordance with the requirements of the church and spiritual need, the Middle Ages saw the development of the martyr biography (e.g., John Foxe's *Book of Martyrs*; Foxe, 1563), and the manifold lives of holy men and women, known as hagiographies. The purpose was didactic and the central character was presented as a model of Christian propriety and public virtue: God's creation was portrayed as an individual who, in the course of a lifetime, developed as a moral example to others, or whose destiny was first fulfilled in death. The borderline between biography and hagiography was broad during the Middle Ages. Christian funeral sermons that focused on the devotional everyday life belief in God included biographical life stories of men and women not belonging to the educated people of culture. Christianity and the Christian biography opened the door to the reception of the hagiographical tradition.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62132-3

At the same time, though, a nonhagiographic model was also used for biographies of princes and emperors, with Eginhard Einhard's *Vita Caroli Magni* (AD 829) frequently cited as being the most important. The secular approach to historical biography was introduced during the Italian Renaissance, a change that continued further afield from the seventeenth up to the nineteenth century. As stated in Christopher Klein (2009), the decisive biographical innovation came from Italy with Francesco Petrarcha's (1304–1374) *De Viris Illustribus* and developed from Giovanni Boccaccio's (1313–1375) sense for the specific, the classical times, and the secular in *De Claris Mulieribus* (1355–1359) and *Vita di Dante Alighieri* (1354–1355). Petrarcha's and Boccaccio's glorification of brilliant individualities connected to the much later liberal individualism in society. Early encyclopedias of women from Germany confirm this tendency. Biographical literature became so extensive during the eighteenth and nineteenth centuries that E. M. Ottinger's (1854) bibliography of biographical literature was only rudimentary, even though it was wide-ranging.

From the end of the eighteenth century, J. Boswell's *Life of Samuel Johnson* (1791) is still singled out as the pioneering biography of the era, as it was based on empirical material in the form of letters, private papers, conversations, interviews, and personal observations of Samuel Johnson's comportment. This was the first biography to construct a nuanced, candid personality focusing on the character of the protagonist. In the historical biography of the time, the history of human achievement was fundamentally the story of imposing male heroes. In the biographical discourse of the nineteenth century, also Thomas Carlyle's lectures *On Heroes, Hero-Worship and the Heroic in History* (1841) have a paradigmatic position claiming 'the History of the World' to be the biographies of great men. Thus claiming biography as a branch of history, and employing similar processes of research and scholarship in the making of biography, he claimed historical biography as essentially the chronicle of an individual's life journey, whereas Boswell and Johnson had claimed it an art of human portraiture. This difference of perception illustrates the eternal question on history versus biography that has hung over historical biography from antiquity to the present days. But still, at the end of the nineteenth century, it was the exceptional (male) person and the developmental process that characterized the 'life-and-letters' biography. Even though ideas and people from the community at large were incorporated into the biographies via reference to letters, and via learned, illustrious, and strange women, there was generally no trace of historical reflection on the individual and society or any change of the skewed gender balance in the genre of historical biography. Here, the Russian G. V. Plechanov was a pioneer introducing the issue of the dynamics between the individual personality and the society as a historical transformation factor with *The Role of the Personality in History* (Plechanov, 1898). The impact of his work in Western historical biography, however, seems to be limited.

The modern life story, as twentieth-century historical biography has been called, came about as the result of the crisis of humanism, Christianity, and rationalism that followed in the wake of Darwinism and psychoanalysis as developed during the nineteenth century. The modern life story in literary history was introduced with L. Strachey's *Eminent Victorians* (1918), which came to play the same revolutionary role for historical biographers of all professions as Boswell had played for biography in the eighteenth and nineteenth centuries: the introduction of the artistic, interpretative biography, given form via selection, concentration, and interpretation of the sources. The idea was to get behind the myth of the subject of the biography and pave the way for the writing of biographies of men *and* women. Another member of the famous Bloomsbury group, Virginia Woolf, went even further in her book *The Art of Biography* (1939). Rather than attempting to escape the limitations of the genre as Strachey had, Woolf urged biographers to endorse them by taking the front position, "testing the atmosphere, detecting falsity, unreality, and the presence of obsolete conventions." The biographer's sense of truth had to be alive, because biography was "only at the beginning of its career; it has a long and active life before it, we may be sure – a life full of difficulty, danger, and hard work" (Woolf, 1939). Thus, both Strachey and Woolf positioned themselves as pioneers in the twentieth-century paradigm of *literary* historical biography. L. Edel (1957) published the most influential postwar study of the biography, which he honed throughout his life's work under the motto "A writer of lives is allowed the imagination of form but not of fact" (Edel, 1984). Literary biography became a well-established genre in its own right (Friedson, 1981). Within this genre, the postmodernists I. B. Nadel (1984), W. H. Epstein (1987), and P. Bourdieu (1989) have sought for a poetics of biography by pointing out that definitive life portraits are not to be found.

Biography could be 'collective,' too, involving a comparison of several lives or a tighter analysis of a number of lives linked through a central theme, such as Plutarch's *Parallel Lives*, Strachey's *Eminent Victorians*, and, in a modern understanding, P. Rose's *Parallel Lives* (1983) on a number of famed English married couples in the nineteenth century, and L. W. Banner's *Intertwined Lives* on Margaret Mead and Ruth Benedict (Banner, 2003).

Biography as a Methodological Approach

By contrast, within the historical and sociological disciplines, the historical biography remained a methodology in understanding the significance of the historical individual and the subjective experience, rather than becoming a genre in itself. Nevertheless, the historical biography vividly developed during the twentieth century, displaying a multitude of biographical methodologies, as documented in P. France and W. St Clair (2002), G. Fromm (1986), J. Le Goff (1989), M. Rhiel and D. Suchoff (1996) and M. Shortland and R. Yeo (1996). Furthermore, the number of published historical biographies increased. Most important was the emergence of the *life-work-and-times* biography, in which the individual was contextualized in the light of contemporary society. A characteristic of the twentieth-century historical biography was that male heads of state, with a few exceptions, still were the focus of interest throughout the century, in spite of the first- and second-wave feminism of the nineteenth and twentieth centuries. Another characteristic was that biographical critique and a theoretical debate on biography as a genre intensified at regular intervals without being carried out systematically. A new aspect was incorporated into the genre: demythologization and unmasking of the protagonist; as Oscar Wilde said, "Formerly we used

to canonize our heroes; today we vulgarize them." Finally, historical biography was influenced by both academics and artists. Thus, serious biographical literature covered the entire spectrum from not very accessible treatises to stylistically inviting reading.

As mentioned, the sociological and historical professions regarded the biography critically throughout the twentieth century even though the publications of historical biographies were manifold (Possing, 2001, 2012b; Rosengren and Östling, 2007; Klein, 2009; Caine, 2010). Historical-sociological biographers and literary biographers began to draw a little closer together after the 1930s. This drawing together continued throughout the rest of the century: literary-framed biography became more scholarly framed, and historical-, sociological-, anthropological-, and natural science–framed biography became more literary framed, claiming that the more objective a biography was, the more lifeless and hollow it became (Kendall, 1965; Madélenat, 1984). The psycho-historical biography did not really establish a firm footing within the humanities and the social sciences, as did the life narratives growing into a paradigmatic trend of mixing autobiography and biography in literature and history at the turn of the millennium.

Sociologists have used historical biography as a methodology for understanding the significance of subjective experience. Pioneers in this respect were F. Znaniencki and W. Thomas (1918–1920), who presented the individuals and groups of individuals as both creative and created in social evolution, thus introducing prosopography. The life history perspective was followed up by the Italian sociologist F. Ferrarotti (1983), who saw the individual as an active pivot in respect to the structures and history of society and B. Merrill and B. West (2009) who reflected on the use of biographical methods in social research. Life histories have also interested late-twentieth-century anthropologists wishing to promote subjective experience as a factor in the creation of personal identity (Crapanzano, 1980). Anthropologists have considered biography to be a participant observer in a cross-cultural and cross-epochal dialogue with the historical subject.

The mentalities-historians also influenced the historical biography, especially the French Annales-school and its preoccupation with personification and its hermeneutic, mentalities-historical studies. In her innovative study of sixteenth-century *Martin Guerre* (1983), N. Zemon Davis used new ideas, concepts, and methodologies from anthropology, ethnography, and literary criticism to examine the dilemma of truth and doubt in historical research. Perception of a central figure became the result of a communicative process between two cultures and two people, not an objective description. Jean-Paul Sartre's concept of interaction between the life lived and the written text inspired the development of the dialectic biography. In Denmark and the Scandinavian countries, the historical figure within this tradition was interpreted as both the bearer of a cultural convention and a cultural agitator (Possing, 1992, 1997, 2001; Klein, 2009). Sociologists, ethnologists, and historians have all used reminiscence, the oral-history tradition, interviews, and private papers as empirical source material via which to understand social action in a wider perspective as a confrontation with the positivist, Marxist, and structuralist thinking that has starved the biography of life. The objective was a demythologization of major figures: "A modern biographer may or may not choose to reveal the intimate, the amorous details of a life, but he must, if he is good at what he does, probe beneath its public, polished self" (Pachter, 1979).

Nonetheless, academic historians were ambivalent about the genre of biography. It remained the professions' unloved stepchild or courtesan (Possing, 2012a), because many historians were skeptical of the capacity of biography to convey the kind of analytically sophisticated interpretation of the past that academics expected. At the turn of the millennium, historians still characterized biography as a degraded form of historical writing.

The Budding Renaissance of Biography

In the light of a quarter century's interest in social history, mentalities-history, and historical narrative, the historical biography, with its focus on the individual above and as part of community, class, and social group, underwent a renaissance. The role of historical biography as a point of orientation in human life was one of several reasons for its popularity as a genre at a time when belief in the great utopias disappeared with the end of the Grand Narratives. Historical biography became the prism for a multitude of preoccupations. The 1990s saw a desire for images of women and men as creative, reflective, doubting, and determining individuals, and a wish to leave behind the tendency to reduce specific singularity to social regularity. More historians, with G. Levi (1989) in the lead, expressed this need for open reflection by pointing out that, more than ever, the ambiguous biography was a central preoccupation for historians. The biography became a sanctuary for the dramatic, old-fashioned narrative amidst a deconstructing and fragmented era. It facilitated reflection on the human ideal in the perspective of the flawed living individual, preventing biography from becoming eulogy.

The renaissance of biography was a manifestation of a genuine renewal of the genre, taking its inspiration from advanced literature and the new gender studies, and from the critical question of the extent and manner in which history is created by people and how a life can be decoded. On the one hand, historical biography made a justifiable demand to set the agenda via a rehumanization of the humanities, which meant that passion, irrationality, and human idiosyncrasy were drawn into an understanding of an individual's life's work (Caine, 2010; Hamilton, 2007, 2008; Klein, 2009). On the other hand, the genre's respectability was contested time and again, and still, it was not secured a serious, scholarly profile. Some maintained that biography chose them while they were engaged in other research. Ambivalence in relation to placing biography as a genre within historiography seemed to be the result of an ongoing opposition to a consideration of single characters. Individual lives, especially the private, were considered as irrelevant or inappropriate to the understanding of history, scholarship, or art by the structuralist, positivist, and postmodern antibiographers.

But in spite of being left out in the cold, the genre imposed itself again and again. This was further illustrated by the reaction of postmodern and structuralist critics such as Jacques

Derrida, Michel Foucault, and Roland Barthes, who called the historical biography "impossible to use as reference," "spurious," "profit-mongering in intimacy," or, conversely, a thanatography – an account of a person's death. Bourdieu used the expression "the biographical illusion" (1986), by which he meant that a life story had no direction and thus could not be construed in a chronological order. Against such criticism, social constructivist historians stressed that a human individual had to be conceived as a part of the surrounding society; that biography did not represent a life as a continuum, but as a construction of many identities; and that historical biography could and should de- and reconstruct a life (Macey, 1993; Margadent, 2000). The biographical turn in history, literature, other sciences, the media, and the entertainment industry became reality at the turn of the millennium.

The Biographical Turn

During the first decade of the 2000s, historical biography underwent a renewal. It exploded in a cornucopia of publications, and historians identified the biographical turn in history. Historical biography changed from an approach in history to an inherently interdisciplinary and self-assertive genre calling itself the 'new biography' (Wagner-Martin, 1994; Margadent, 2000). This was especially influenced by feminists, postmodernists, and race theorists. Feminists and postmodernists focused on the diversity and complexity of personalities, movements, and institutions, decrying 'essentialism',. Theorists of race focused on the marginalized black and Afro-American groups who had suffered oppression and discrimination, raising broader issues on transnationalism in postcolonial studies. Already during the twentieth century, historical biography as a field of interest had developed from a conscious mythologization of prominent, historical figures to a critical, manifold storytelling of public, national, transnational, and anonymous historical lives.

In the light of the abundance of publications that emerged during the first decade of the third millennium, the biographical genre can be understood from two perspectives. *Firstly*, historical biography has been despised and looked upon with condescension, despite the fact that in the international forum it is a 2000-year-old genre (Egeland, 2000; Hamilton, 2008). Although not gaining respect or dignity, paradoxically scholars and journalists have produced a cornucopia of biographical works during the last 20 years. Historical biography seems to be much appreciated by the general audience. It is like a courtesan, in constant demand and much visited, but taboo and referred to with disrespect by academic society. As the courtesan is visited by men, so too the biography has been preoccupied with men. Statesmen, kings, financiers, scientists, scholars, and authors of the male sex have populated the genre, which has only within the last decade become properly accessible to women and ordinary, anonymous people (Larsson, 2001; Banner, 2003; Huismann et al., 2012; Possing, 2012b). The well-known gender imbalance of the historical biography is changing and has altered with the biographical turn in history, with more historical biographies having female protagonists or female biographers. This phenomenon was pioneered by authors and scholars with experience from the modern fields of women's history and gender studies (Alpern, 1992; Possing, 1992; Moi, 1994; Larsson, 2001; Banner, 2003; Benhabib, 2003; Hirdmann, 2006).

Secondly, historical biography underwent a major renaissance at the end of the twentieth century – in the Scandinavian countries, all over Europe, and in most of the Western world. It exploded as part of the popular 'experience economy' and in academic culture. Since the turn of the millennium, the spirit of our times has been colored by 'the biographical turn' (Hamilton, 2008; see also Caine, 2010) and "le retour de la biographie" (Arnaud, 1989; Klein, 2009). This can be explained as an element of the individualistic or individualizing zeitgeist following the demise of the Grand Narrative. In present days, there is hardly a conference or a symposium in the area of the humanities and social sciences that does not have a session or a paper on the subject of biography. National and international networks of autobiographical and biographical authors and scholars are blooming. Also, autobiography and the myriad forms of life stories and narratives have exploded as a sphere of interest.

The parameter for the evaluation of a historical biography is most often the dialectical *life-work-and-times* biography with a balanced analysis of the individual situated in the larger context, or with an analysis of the power structure and the dynamic interplay between the individual and the society. Most are based on archival material and some even on detective-like research. Some historical biographies skew the depiction perspective at the expense of historical analysis; others focus on more simple life depiction at the expense of analysis (Rosengren and Östling, 2007; Banner, 2009).

The historical biography can also be written as a *prism* in which the light of history is refracted and the perspective raises the central figure as representative of a time, a historical situation, a type, a social phenomenon, or a culture. Or it can be written as a *collective or relational biography* comparing more lives as in the tradition of Strachey (1918) and Rose (1983), and as seen in Banner (2003) or in Anneke Ribberink's comparison of prime ministers Margaret Thatcher and Gro Harlem Brundtland (Huismann et al., 2012).

Challenges in the Wake of the Biographical Turn

At the turn of the millennium, the historical biography was in the process of redeveloping 'l'ecriture historique,' historical writing. After the biographical turn in history, the challenge of the historical biography changed. Despite the biographical flood, there was no well-developed critical tradition. Neither universities nor schools of higher education offered specific training in the all-round study of biography: "Its ethics, like the history and theory behind it, thus go largely unaddressed, while at a practical level there are still relatively few courses offered to those who wish to write a biography, whether big or small. Would-be biographers are thus left largely to their own devices, scrabbling for advice and examples in every direction," the British biographer and historian Nigel Hamilton wrote in 2008. Biographers from Plutarch to Ian Kershaw, the biographer of Hitler (Kershaw, 2008), have hard-won experiences in depicting real lives, and in representing their stories in historical biographies. Experiences from the reconstructions of human life and the representations of historical individuals

through 2000 years have shaped biographical conventions. Traditionally, every biography is a life from cradle to grave; every biography has an intention, a plot, an agenda, or a motive beyond that of telling a life; every biography is shaped by the biographical triangle (the relation between the biographer, the protagonist, and the audience); and every biographer holds the fate of someone else in their hands. At the biographical turn in history, all these four conventions are being both challenged and used by present historical biographers. The biographical turn not only happened because of the post-Freudian Western world's inclination to psycho-historical analysis. It also happened because the historical biography became part of the democratic project in an increasingly globalized community. Historical biography expresses interest in the individual, and his or her place in culture and society.

The new knowledge of the historical biography is to be found in the *interdisciplinary analytic field* known as biographical studies. This field distinguishes between the *genre*, this being the empirical narratives of individual lives as they can be read from antiquity to the present day, and the *academic discipline*, which this genre comprises. The biographical sphere is by its very nature interdisciplinary, because a single historical biography borders on many other genres, subjects, and narrative traditions; it raises the issues of politics, social relations, economics, culture, ancestry, kinship, family, sexuality, psychology, and friendship (Klein, 2009).

Thus, the historical biography has turned into an interdisciplinary sphere and a genre, placed in a battlefield of multifarious narrative forms. Only lately have biographers started a theoretical work of building bridges between types, intentions, methodologies, and narrative techniques. Historical biography is in the frontline of tackling an unwieldy ethical accountability vis-à-vis an increasing public pressure on the right to invade the private lives of public personalities (King, 2001; Rollyson, 2005; Baets, 2009, 2010). And last, but not least, the historical biography is in the vanguard of understanding the influence of the inclusion of women in the public arena to twenty-first-century changes in the genre that during the twentieth century was called 'the science of man' (Edel, 1957; Huismann et al., 2012).

Biological Preconditions for Language Development

Jutta L Mueller, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany; and University of Osnabrück, Institute for Cognitive Science, Osnabrück, Germany

Abstract

Language, an elaborate system of discrete units and combinatorial rules, builds on complex neurocognitive foundations. Language development results from both maturation and learning. Specifically, learning mechanisms are implemented in brain networks that are still in the process of structurally and functionally maturing during the first year of life, which is the focus of this review. We will first sketch basic language-learning skills that provide the biologically grounded foundation of language development and expound their neural implementation. Subsequently, we will outline neural maturation in language-relevant brain areas and how this might relate to the way language development proceeds.

Early Speech and Language Abilities

Discrimination of the Sounds of Language

At the core of language acquisition research is the question of whether we are biologically prepared to process human language in a special way. Early behavioral research has shown that newborns can discriminate their native language from a rhythmically different language (Mehler et al., 1988) based on prosodic information. Findings showing that they can also discriminate between two rhythmically different nonnative languages that are unrelated to their native language (Nazzi et al., 1998) indicate that this is a universal perceptual ability. Not only can newborns differentiate between language and similarly complex nonlanguage stimuli (Vouloumanos and Werker, 2007), they can also discriminate phonemes of any human language in a categorical manner (Eimas, 1975). This ability develops from an early general ability to discriminate all phonemes, even from unfamiliar languages, into the ability to discriminate only native language phonemes toward the end of the first year of life (Werker and Tees, 1984).

Given that early sensitivities with regard to auditory linguistic input have been demonstrated, the question arises as to whether infants engage a similar neural substrate to adults when they listen to language. Neuroimaging studies during the first 3 months of life comparing language stimuli with acoustically matched nonlanguage stimuli have shown left-hemispheric activation for language in similar fronto-temporal brain regions as was found for adult language processing (Dehaene-Lambertz et al., 2002; Peña et al., 2003). Furthermore, the native language was specifically shown to already elicit left-hemispheric activation a few days after birth (Sato et al., 2012). Nonetheless, the infant language network may be at an immature stage. Perani et al. (2011) conducted a functional connectivity analysis in adults and infants, who were only 3 days old, focusing on 'cross-talk' between different brain regions while the participants listened to language, and reported marked differences between the adult and the infant brain. While the adult brain showed strong intrahemispheric fronto-temporal connectivities, the infant brain showed only interhemispheric connectivities (Perani et al., 2011). Yet, the involvement of similar brain regions in infants and adults speaks in favor of a biological preparedness to process familiar linguistic stimuli in a specialized network. The crucial signal invoking this network may be contained in the acoustic, rather than linguistic, properties of the speech signal. A study looking at the processing of temporal acoustic information reported more left-hemispheric contributions to the processing of fast acoustic modulations compared to slow modulations (Telkemeyer et al., 2009). This supports the notion that the speech signal, which is characterized by fast acoustic modulations between phonemes, triggers left-hemispheric processing mechanisms that might be innately specified. Yet, as there is evidence that there is already some fetal language perception (Smith et al., 2003) and memory for language (Decasper and Spence, 1986) in the last trimester of pregnancy, these results do not completely rule out that early left-hemispheric specializations are due to language experience in the womb.

In a similar way, later developmental steps taking place during the first year of life may also be subject to both biological maturation and linguistic experience. Recent studies with preterm infants, who show comparable postnatal linguistic experience but delayed neural maturation due to their lower gestational age, have provided interesting evidence concerning the interplay between the two. Peña et al. (2010, 2012) reported that the onset of linguistic abilities, such as the discrimination between the native language and a rhythmically similar language, and discrimination between nonnative phonemes, is determined by maturational status, rather than by experience. However, there are converse findings from a study on the perception of consonantal patterns, which reports clear effects of experience in preterm infants (Gonzalez-Gomez and Nazzi, 2012), supporting the idea that such 'experience vs maturation effects' are highly dependent on the exact linguistic feature under scrutiny. However, it is not only global neuronal maturation, as measured by gestational age, which can be used as a measure for the impact of maturation on the timing of language learning. Also, specific physiological parameters, for example hormonal measures, have been shown to affect basic language perception mechanisms. Friederici et al. (2008) were able to show that boys' discrimination of phonemes at the age of 2 months was influenced by their blood testosterone level, higher testosterone levels being linked to reduced ability to discriminate

phonemes. Such studies show that global measures, as well as specific maturational ones, can be related to the timing of the appearance of basic mechanisms of language perception.

Word Learning

Infants produce their first words around their first birthday and it is only later, at the age of 18–24 months, that the well-known sudden increase in vocabulary, the so-called vocabulary spurt occurs. Yet, indications of word recognition are reported much earlier. Infants at the age of only $4^1/_2$ months recognize highly frequent words such as 'mommy' and 'daddy' (Mandel et al., 1995) and from 6–9 months of age infants are able to grasp some aspects of referential meaning (Parise and Csibra, 2012; Bergelson and Swingley, 2012). The question is, which learning mechanisms allow young infants to detect and segment words from ambient speech and how are they rooted in the neural system? Two basic kinds of cues have been suggested to possibly assist segmentation of words. These are statistical and acoustic cues. Statistical learning of word boundaries, for example, the use of transitional probabilities between syllables to segment words has been demonstrated to start from the age of 7 months, in studies using behavioral measures (Saffran et al., 1996; Thiessen and Saffran, 2003), and to start from the age of 2 days, in studies using electrophysiological measures (Teinonen et al., 2009). Although the phenomenon of statistical word segmentation is undisputed, it is still unclear what role it plays in word learning during natural language acquisition. Recent findings show that word forms that have been segmented via statistical learning are preferentially used for the mapping of meaning (Estes et al., 2007; Hay et al., 2011). This supports the idea that statistical learning has the potential to play a role during natural word learning: Because statistical learning is present from the onset of the language acquisition process, it might well be one of the driving forces of language learning. Future studies face the challenge of specifying the neural basis of statistical learning in early infancy.

Besides mere statistical cues, the acoustic features inherent in spoken language, such as word stress, have been shown to be important cues for word segmentation in infants (Jusczyk et al., 1999). Infants are sensitive to language-specific prosodic realizations of words from early on. For example, a study with 4–5-month-old French and German infants found that they already show differing electrophysiological brain responses as a function of language-specific word-stress patterns (Friederici et al., 2007). An intriguing related finding is the observation that infants' cry patterns seem to reflect their native language's stress pattern (Mampe et al., 2009), indicating that even newborns are sensitive to their language's stress pattern.

Despite all these findings about astonishing language abilities in early infancy, not much is known about the brain structures supporting early learning of word forms. Benavides-Varela et al. (2011, 2012) tested the learning of simple CVCV word forms (e.g., 'mita,' 'pelu') in a familiarization-test paradigm in 1–4-day-old infants, while they recorded their hemodynamic brain activation using near-infrared spectroscopy. The infants could retain the sound of a spoken word form for a couple of minutes, which was reflected in a decrease of activation in a widespread brain network including frontal, parietal, and temporal areas (Benavides-Varela et al., 2011). A subsequent study extended these findings by showing that neonates' early word form memories rely on vowel information and not on consonantal information (Benavides-Varela et al., 2012).

As a next step in word learning, infants are prompted to understand word forms as referents to the world surrounding them, for example, as labels for objects. Initially, it was assumed that infants can only do so at 9–10 months of age, once they start to grasp that speakers have referential intentions (Carpenter et al., 1998). However, Bergelson and Swingley (2012) found that even 6–7-month-old infants know the meaning of some words, because they looked longer at named than unnamed pictures. It has also been shown that after only a few presentations, children this age can map new word forms onto visual objects (Friedrich and Friederici, 2011; Junge et al., 2012), with prosodic information supporting this process (Shukla et al., 2011). Interestingly, Parise and Csibra (2012) were able to show that young children's word knowledge does not merely reflect audiovisual associations, but also referential understanding.

Together, these findings suggest that word-like linguistic units can be segmented and retained for some time starting at early infancy and that the brain may use domain-general statistical mechanisms in concert with language-specific acoustic cues to achieve this task. In the second half of their first year, infants start to grasp the referential meaning of words and use them as labels for the world surrounding them.

Grammar Learning

Production of grammatical utterances starts after the production of the first words. Yet, similar to word recognition, infants show sensitivity to properties of the language input coding grammatical aspects of language already within the first year of life. Those initial sensitivities may play a crucial role in detecting the basic grammatical patterns in the native language onto which grammatical functions are mapped at a later stage. As already pointed out, newborns are very sensitive to prosodic aspects of speech, such as word stress. Word stress is not confined to assisting word segmentation; it also systematically varies according to grammatical word class. Function words, such as 'the,' 'in,' and 'on,' differ acoustically from content words such as 'window,' 'head,' and 'pen,' with respect to stress and duration, for example. Newborns have been shown to be able to differentiate between the two word classes based on their acoustic differences (Shi et al., 1999). Not much later, at the age of 2 months, sentence intonation can be used to remember word order for a short time interval (Mandel et al., 1994).

Concurrently with their sensitivity to acoustic aspects of language, young infants are already sensitive to structural rules that go beyond mere word segmentation. Neonates were shown to process sequences that contain syllable repetitions (e.g., 'mu ba ba') differently from sequences without repetitions (e.g., 'mu ba ge') (Gervain et al., 2012, 2008). However, syllable repetitions may only play a minor role in natural language processing. Grammatical relations in natural language are often carried by dependencies between distant units of speech, so-called non-adjacent dependencies, as, for example, in 'she smiles.' Behavioral evidence has shown that the learning of

such nonadjacent dependencies occurs only after 1 year of life (Lany and Gomez, 2008; Gòmez and Maye, 2005). Electrophysiological studies have provided evidence that nonadjacent dependencies can be extracted from nonnative sentences, as well as from artificial syllable sequences, at a much earlier age, namely between 3 and 4 months of age (Mueller et al., 2012; Friederici et al., 2011). Interestingly, the ability to extract nonadjacent dependencies has been linked to the developmental status of basic auditory processing (i.e., pitch discrimination) in 3-month-old infants. Only infants who showed electrophysiological indication of more mature auditory processes showed evidence of nonadjacent dependency learning (Mueller et al., 2012). This finding underlines the scaffolding role of acoustic cues and auditory functions for the acquisition of grammatical structures. The reviewed studies have shown that infants process some grammatical aspects of language, so long as they are carried by salient auditory features of the input, from early on. What emerges during the first year of life is most probably a kind of a 'raw grammar' based on phonologically represented rules onto which syntactic functions, which guide thematic interpretation, can be mapped at a later stage during development.

There is an ongoing debate over the kind of learning mechanism needed to extract grammatical rules in language. Specifically, there is disagreement on the question whether one single associative/statistical learning mechanism suffices to explain both adjacent and nonadjacent dependency learning (Pacton and Perruchet, 2008; Seidenberg et al., 2002; Laakso and Calvo, 2011) or whether an additional rule-based mechanism has to be assumed (Peña et al., 2002; Endress et al., 2007; Marcus et al., 1999). It has been argued that some positional effects (Endress et al., 2007), as well as generalizations (Peña et al., 2002; Marcus et al., 1999), cannot be captured by statistical learning alone. Opposing this view, Pacton and Perruchet (2008) were able to show that in adults the joint focus of attention, which is thought to relate the to-be-learned elements to each other, is both a necessary and sufficient factor, irrespective of temporal contiguity of the elements. This speaks in favor of the more parsimonious assumption of a single associative learning mechanism. Whether such an attention-based mechanism is at work in very young infants remains to be demonstrated. If there is a separable rule-learning mechanism, it seems to be present at birth (Gervain et al., 2008).

What is clear is that the language learning mechanism(s) operate(s) in concert with developing perceptual abilities on the acoustically structured linguistic input. This leads to the emergence of quite sophisticated representations of linguistically relevant units and rules of the native language during the first year of life.

Neural Substrate for Language Development

The general idea that brain maturation is closely linked to language development has a long tradition, which has recently gained a new momentum as methods of brain imaging have started to be used extensively in studies of infancy and childhood (Lenneberg, 1967; Pulvermuller and Schumann, 1994; Thompson-Schill et al., 2009; Friederici, 2009; Penfield and Roberts, 1959; Amunts et al., 2003; Pujol et al., 2006; Paus et al., 1999). Proposals regarding the relation between brain maturation and language development can be roughly split up with respect to their explanatory focus. While some theories, especially the older ones, have drawn on brain maturation as an explanation for children outperforming adults as language learners (Penfield and Roberts, 1959; Lenneberg, 1967; Pulvermuller and Schumann, 1994; Thompson-Schill et al., 2009), the majority of brain imaging-based ideas assume that proceeding maturation of certain brain areas causes, or at least parallels, important developmental steps in language acquisition (Friederici, 2009; Dubois et al., 2008; Amunts et al., 2003; Paus et al., 1999). If one accepts the idea that language recruits a specific neural network, which most researchers do, it logically follows that the maturation of that network has an impact on language development. Yet, showing the relation between structural maturation and language processing mechanisms is not trivial because the former cannot be experimentally manipulated. For this reason, experimental evidence is necessarily correlative, at best. As our present review focuses on language development during the first year of life, we will outline what is known about structural brain development in language-relevant areas at and around birth, although brain maturation continues well into adolescence and even adulthood. Up to a few decades ago, brain structure could only be visualized in postmortem studies. Recently developed brain imaging methods have made it possible to quantify properties of white and gray matter *in vivo* and noninvasively in participants of different age groups. While sophisticated analyses of postmortem brains continue to contribute important information about brain maturation, *in vivo* measurements have made the study of structural brain maturation easier than ever been before.

In the mature brain, a mainly left-hemispheric perisylvian network, including frontal, anterior, and posterior temporal brain areas, hosts language processing. These cortical areas are connected via two major fiber pathways: one running dorsally, connecting the pars opercularis of Broca's area, the motor cortex, and the mid-posterior temporal cortex, and the other running ventrally, connecting the pars triangularis of Broca's area with temporal cortical areas (cf Friederici and Gierhan, in press; for review, Gierhan, in press). In adults, one can find a hemispheric asymmetry with the language-dominant left hemisphere showing enhanced white matter density (Pujol et al., 2002; Catani et al., 2007). Coming from a developmental perspective, we will discuss two questions: the maturation of language-relevant cortical brain areas and pathways, and hemispheric lateralization during development. As pointed out in Section Discrimination of the Sounds of Language, perisylvian language areas have been shown to be selectively active during language processing from shortly after birth, which is suggestive of the language system of the brain already being in place before the onset of extensive linguistic experience. Yet, in order to fully characterize the biological basis of language, it is important to know whether the functional and behavioral sensitivities are building on a mature and specialized brain structural basis or, alternatively, whether the structural basis develops later with increasing linguistic experience.

Frontal cortical regions reach adult levels of maturation relatively late, as anatomical studies using postmortem brains

have shown (Huttenlocher and Dabholkar, 1997; Amunts et al., 2003). Thus, it came as a surprise when a study found that frontal cortices were activated while infants who were only 3 months old listened to language (Dehaene-Lambertz et al., 2002) and these activations could even be observed in younger infants (e.g., Perani et al., 2011). This indicates that the relative neuroanatomical immaturity does not make the frontal cortices functionally silent, but suggests that they may not yet serve the same function that they do in adults. The auditory cortex, which shows much faster maturation compared to the frontal cortex, also continues to mature until late childhood (Moore and Linthicum, 2007). Brain imaging studies that quantify brain maturation based on anatomical brain scans sometimes come to different conclusions than postmortem studies. One of the basic processes of brain maturation, myelination (i.e., the progressive coverage of axons with an insulating sheath of glia cells), seems to proceed at a similar speed in temporal and frontal white matter during the first year of life, but fiber bundles connecting different brain regions mature at a different speed (Pujol et al., 2006). Interestingly, the arcuate fascicle, that connects Broca's area in the inferior frontal gyrus and the posterior temporal cortex, develops relatively late. The study of Pujol et al. (2006) is one of the few studies of early development that shows a correlation with a measure of linguistic performance, in this case vocabulary size. The vocabulary spurt coincided with reaching a high percentage of myelination in temporo-frontal areas, which leads to speculation about the relation between perisylvian myelination and the course of language development.

A recent MRI study quantifying gray matter maturation (including, for example, myelination, and axonal and dendritic growth) in 1–4-month-old infants reported correlated maturation of posterior temporal cortex and Broca's area, with the temporal cortex lagging behind (Leroy et al., 2011). The significant correlation between those gray matter results and previous discoveries concerning white matter data (Dubois et al., 2009) led the authors to conclude that the dorsal language pathway is mature from early on (Leroy et al., 2011), although the frontal portion of the pathway was not identifiable. Another study, which focused on the dorsal pathway as a whole, was able to show that the fiber bundle that anatomically connects posterior temporal regions to Broca's area is not yet present in newborns (Perani et al., 2011), but another dorsal fiber tract that connects the posterior temporal cortex with premotor cortex is. Moreover, with respect to functional connectivities, the aformentioned study by Perani et al. (2011) demonstrated that infants, in contrast to adults, showed no intrahemispheric long-range functional connections. This finding strongly suggests that, despite the functional responsiveness of the single parts of the language network at and shortly after birth, the anatomical and functional connectivities within the network are far from adult-like and still have to be established during the course of language development.

What does the relative immaturity of the connections to the frontal cortex mean for language development? Possibly, as has been suggested above, it means that language learning in early infancy is a rather sensory-guided enterprise. The auditory cortex has been shown to be able to extract quite complex and even abstract auditory patterns (Bendixen et al., 2008), and it can be reasonably assumed that many of the early language learning abilities that have been outlined above can be managed by the auditory cortex alone. Efficient interplay between frontal and temporal language areas becomes especially important when syntactically complex sentences have to be processed (Friederici, 2009). However, this ability is not fully developed until later childhood, because even 6-year-olds (Schipke et al., 2012) and 7-year-olds (Dittmar et al., 2008) have difficulties processing, for example, object-initial sentences. In this context, it is interesting to note that in 7-year-olds the arcuate fascicle and the superior longitudinal fascicle, connecting Broca's area and the temporal cortex, are still not fully matured (Brauer et al., 2011). This is relevant in so far as this fiber connection has been shown to support the processing of syntax (Wilson et al., 2011).

One of the basic features of the brain's language areas is their structural and functional lateralization. As lateralized functional activation has been reported to exist early on, whether this builds on an already lateralized anatomical substrate is an important question. Lateralization clearly undergoes maturation. The left–right asymmetry in Broca's area, as measured by cytoarchitectonic profiles, was shown to be fully adult-like only at the age of 11 years (Amunts et al., 2003), whereas left-lateralized white matter maturation in the dorsal pathway has been shown across childhood (Paus et al., 1999). Despite these findings of an extended period of lateralized maturation, a left–right asymmetry in the gray matter was shown for both the frontal and the temporal language regions, even in preterm infants (Dubois et al., 2010), suggesting an anatomical prerequisite of lateralization that might set the basis for later functional lateralization. This corresponds to earlier postmortem studies on gray matter lateralization that reported asymmetries in temporal language areas during the last trimester of gestation (Chi et al., 1977).

These findings show that gross anatomical properties of some white matter pathways for speech and language, and some degree of lateralization, are already present from birth. However, the protracted maturation, especially of the dorsal pathway, may underlie some of the differences observed in language learning between infants and adults. It has been suggested that infants learn in a much more bottom-up, sensory-guided way than adults, who instead engage prefrontally guided processes of cognitive control. For infants, this might be, with respect to the final outcome, the more efficient way to learn conventional patterns such as language (Thompson-Schill et al., 2009). Although there is not much direct evidence for this hypothesis, the anatomical substrate found at and after birth supports this notion, because the relative immaturity of the fiber pathways speaks for initial sensory-guided language development.

Conclusion

The infant brain is predisposed to learn language starting from birth and even earlier. Behavioral and neurophysiological methods have revealed infants' astounding sensitivities to linguistic stimuli, as well as impressive abilities to learn aspects of words and grammar from early on. While important neural

characteristics of the language network, such as functional specification of fronto-temporal language regions and hemispheric specialization, are present from early on, they continue to mature in important aspects. Although the whole language network is active during language processing in early infancy, the relative immaturity of the dorsal fiber pathway might contribute to the observation that the earliest language learning processes happen in a bottom-up, sensory-guided manner.

Biomarkers in Demographic Research

Thomas McDade, Northwestern University, Evanston, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The integration of biological measures into demographic research bridges the gap between field- and clinic-based approaches to understanding human health, and it has the potential to transform the study of human biology. This article discusses the benefits, as well as potential costs, of collecting biomarker data in large-scale, social science surveys. It reviews methodological options for field-based biomarker data collection, and highlights recent applications to demonstrate their utility for promoting innovative research into the causes and consequences of human biological variation.

Introduction

Social, cultural, economic, and other environmental factors are widely recognized as critical determinants of health and disease, and the causes and consequences of variation in health have long been topics of central interest to demography. But disciplinary traditions, and challenges associated with collecting biological data from large numbers of people, are such that the vast majority of demographic research on health relies on vital records or self-report methods. In contrast, biomedical research employs sophisticated measures in controlled clinical or laboratory settings, but typically relies on small clinic-based samples and rarely evaluates social contexts beyond standard measures of socioeconomic status or self-reported health behaviors.

Integrating biological measures into demographic research bridges this gap, and promotes efforts to understand the biological pathways through which social, economic, and community factors shape population health (Seeman and Crimmins, 2001). The expansion of methodological options for collecting biological samples in nonclinical settings has greatly facilitated this effort, and encouraged a growing number of social scientists to include biological measures in large-scale surveys (Finch et al., 2001; Weinstein et al., 2008).

The objective of this article is to discuss the benefits, as well as potential costs, of integrating biomarkers into demographic research. The types of biological data that can be collected in community-based settings, as well as methods for collecting them, are briefly reviewed. A handful of demographic studies are discussed in order to showcase the potential of integrating biological measures into large-scale, social science surveys.

Why Biomarkers?

Biomarkers are directly measured traits that provide information on the functioning of biological systems. They cast light on normal biological processes, as well as pathological processes that indicate the presence of clinically identifiable disease, or an increased risk of disease in the future. Many biomarkers require the collection and subsequent analysis of biological specimens (e.g., blood, saliva, urine), while others rely on physical and functional measures (e.g., blood pressure, anthropometry, grip strength).

The vast majority of research on human biology and health is conducted in clinical or laboratory settings, or with focused epidemiological cohorts. Indeed, much of what is assumed to be known about human biology does not even involve humans, and is based on research with animal models. By collecting biological data from large, representative samples in diverse community-based settings, investigators can better understand the population distribution of health and disease, shed light on the individual, household, and community-level variables that account for this distribution, and identify trends that can be used to predict future patterns of morbidity and mortality. Several conceptual models have been proposed to facilitate our understanding of the biological pathways through which contextual and behavioral factors shape population health, and the measurement of biomarkers is central to this effort (Seeman and Crimmins, 2001; Glass and McAtee, 2006; McDade et al., 2007). Applications representing particular theoretical, disciplinary, or practical interests will focus on a subset of these pathways, with much higher resolution on the exposures and outcomes of primary interest.

There are at least five reasons why direct measurement of biomarkers has the potential to advance population-based research on human biology and health. First, self-reports of health (general health, as well as more specific reports of symptoms, diagnoses, and functional limitations), as well as information contained in vital and clinical records, have comprised the primary sources of data for health-related research in demography. These sources provide information on the distribution of important health outcomes, but biomarkers are necessary to illuminate the specific biological pathways through which socioeconomic, demographic, and psychosocial factors lead to these outcomes. In addition, biomarkers can help identify which aspects of psychosocial and physical environments are most damaging to health, as well as point toward resiliency factors that buffer subsets of individuals from the damaging effects of these exposures. Conversely, biomarkers may provide insight into the extent to which biological processes shape individual life course trajectories and inform selection into various social and physical environments.

Second, biomarkers provide direct information on pathophysiological processes that contribute to the development of disease, before clinically diagnosable problems are evident. For

example, prospective studies of cardiovascular disease (CVD) indicate that relative levels of CVD biomarkers (e.g., blood pressure, lipids) tend to remain stable, or 'track' from childhood into adulthood (Berenson et al., 1995; Li et al., 2004). While biomarker measurement earlier in life may not uncover many clinical cases of CVD, attention to predisease pathways will identify individuals most at risk for the future development of disease. Along these lines, biomarkers can help identify which physiological pathways in particular (e.g., aspects of neuroendocrine, cardiovascular, metabolic, and/or immune function) are most involved in the health outcomes of interest.

Third, biomarkers typically represent more direct and objective measures of health, and are therefore not susceptible to many of the limitations and biases associated with more subjective self-reported health measures. Biological measures typically do not rely on participants' ability to report on relevant aspects of their health, or their willingness to share this information. Biomarkers may be useful for validating self-reports of health, but most often their utility comes from offering access to embodied information that is below the threshold of perception, but that is nonetheless meaningful for physical health. This is a particular advantage for settings where accurate information on self-reported health may be especially difficult to obtain, as in research with children, or across international settings where linguistic and/or cultural factors may contribute to variation in the perception, experience, and/or reporting of health (Hahn, 1995; Kleinman, 1986).

Fourth, the methodological options for field-based biomarker research are rapidly expanding (see below), further encouraging the collection of biological data from large numbers of participants in diverse community-based settings. Larger, more representative samples increase the generalizability and potential policy impact of research findings, and help identify subgroups of individuals, or subsets of environments, that merit special attention. Population-based biomarker research also encourages an epistemological shift that reframes the study of human biology as a holistic, integrative endeavor that foregrounds contextual factors as potentially important contributors to variation in human physiological function and health across the life course (Stinson et al., 2012).

Lastly, the integration of biological measures into demographic research promotes productive collaboration among social, life, and biomedical scientists. Health is a complex, multidimensional phenomenon that articulates with human experience in dynamic ways over the life course. Collective efforts that bridge disciplinary boundaries can be significant sources of innovation that advance our understanding of human biology and health, as well as the psychosocial, behavioral, and cultural contexts within which it is embedded.

While the scientific payoff to including biomarkers in demographic research is potentially very high, important caveats should be kept in mind, particularly for investigators involved in designing data collection efforts. First, biological measures add to respondent burden, and may impose additional risks to research participation. Burdens and risks vary across methods of sample collection, and in most field-based applications they are relatively minimal. But even minimal risks need to be taken seriously, and for some participants the actual or perceived risk may be higher. It is therefore important to consider the implications of biomarker protocols for sample recruitment and retention. It is worth noting, though, that for many research participants burdens associated with biomarker collection may seem less onerous or problematic than the psychological discomfort associated with disclosure of embarrassing or otherwise sensitive information. For example, in the Add Health study (discussed below), 94% of participants were willing to provide a finger-stick blood sample, but only 93% would report their income.

Second, biomarkers can be costly, and they add to the logistical challenges associated with data collection. Some measures, like height or waist circumference, can be relatively easily implemented by survey interviewers. The collection of finger-stick blood or saliva samples can also be done by interviewers, but only after adequate training in sample collection and handling to make sure collection is done safely and effectively. Biological samples also need to be handled and transported in ways that maintain sample integrity prior to analysis in the lab, which adds to the logistical complexity and costs of data collection. And once in the lab, analysis costs typically range from approximately $10 to 30 per biomarker per sample, which can add up quickly, particularly for demographic surveys with large numbers of participants.

Lastly, as with any human subjects research involving potentially sensitive information, biomarkers raise important ethical issues that require careful consideration (Botkin, 2001). Strategies for addressing these issues should be informed by the biomarkers being measured, the populations involved in the research, and the requirements of institutional review boards, which can vary substantially.

Methodological Challenges and Innovations

Demographic studies often have to trade off numbers of participants against depth of measurement, particularly with respect to biological measures. Few field-based studies will be able to achieve the resolution that is possible in controlled clinical or laboratory settings, but the rapidly expanding range of 'field-friendly' biomarker methods is bridging this gap. This section reviews the methods and measures that have been applied in demographic research, and their potential contribution for illuminating biological processes of relevance to population health. More comprehensive reviews on this topic provide more details on these methods, as well as references to validation studies and prior applications (McDade et al., 2007, Lindau and McDade, 2007).

Anthropometric and Functional Measures

Anthropometric measures of body size and composition have been used for more than a century to capture energy balance, nutritional history, and risk for diseases associated with under- and overnutrition (World Health Organization, 1995; Gibson, 2005). Measures like height, weight, skinfold thicknesses, limb lengths, and waist and arm circumferences can be taken quickly with portable equipment at minimal cost, using standardized methods and reference data that enhance reliability, comparability, and interpretation.

Grip strength – a related functional measure of muscle strength – has recently been incorporated into several population-based studies, particularly studies of health and aging. Grip strength can be assessed with a small handheld dynamometer, and has been shown to predict general health, as well as bone density, mobility, physical function, and long-term mortality. Additional functional measures that can be relatively easily implemented in the field, and that predict physical decline and health, include the chair stand and timed get-up-and-go exercises.

Anthropometric measures like body mass index and waist circumference provide integrated measures of energy balance, but accelerometry and heart rate monitoring can be used for more precise estimates of physical activity and energy expenditure on an hourly or daily basis. Accelerometers are of the size of wristwatches that are worn on the wrist, ankle, or waist, and heart rate monitors are worn on the chest. Both methods record the frequency, intensity, and duration of physical activity as participants go about their normal routines, which may be particularly useful for research on obesity and sleep.

Pulmonary function can be assessed in nonclinical settings using portable spirometry devices that provide measures of expiratory volume, expiratory flow, and lung capacity. Measures of lung function are used clinically to diagnose and monitor asthma and obstructive pulmonary diseases, and in population-based settings impaired lung function predicts functional decline and mortality and may therefore be of relevance to studies of health and aging.

Impairments in hearing and vision affect quality of life and predict increased mortality risk. Self-reports are poor indicators of hearing, and audiometry provides more accurate measures of hearing loss that have been successfully implemented in population-based studies. Field-based assessments of visual acuity using standardized charts are feasible, but face challenges associated the need for sufficient space and lighting during implementation.

Blood Pressure

Arterial blood pressure provides an example of a biomarker with direct clinical relevance that can be applied to field-based research with relative ease. Blood pressure is measured clinically to diagnose hypertension, and to predict subsequent risk of coronary heart disease, stroke, dementia, and kidney failure. Smoking, physical activity, diet, and psychosocial stressors are all determinants of systolic and diastolic blood pressure. Noninvasive measures of blood pressure using manual or automated sphygmomanometers can be implemented by interviewers in field-based settings, with results that approximate the clinical standard. Measurements are typically taken two or three times with participants sitting comfortably, and results averaged for a measure of resting systolic and diastolic blood pressure (the first reading is discarded in some protocols). Pulse rate is often recorded along with blood pressure, and can also be used as a measure of cardiovascular risk.

Ambulatory monitoring of blood pressure is also possible, using portable battery-powered instruments worn by participants as they go through their normal daily routines. Frequent measures over a 24-h period can provide a more accurate measure of average blood pressure, assessment of blood pressure variability, differences in blood pressure across the day and night, and information on associations between blood pressure and specific events, contexts, or emotional states.

Measures Involving Biological Specimens

Anthropometric measures, physical exams, and functional tests provide valuable information on human biological function and health, but many important biomarkers are accessible only in biological specimens. In most cases, blood collected via venipuncture represents the gold standard for biomarker measurement, but the costs, invasiveness, and logistical challenges associated with venipuncture are major impediments to blood collection in field-based research. Fortunately, there are alternatives: finger-stick whole blood, saliva, urine, and hair all provide opportunities for collecting biological specimens in demographic surveys. While each type of specimen has its own challenges and limitations, in certain applications these methods may facilitate biomarker measurement in studies where it would not otherwise be possible.

Dried blood spots – drops of capillary whole blood collected on filter paper following a simple prick of the finger – represent a viable alternative to venipuncture that has recently been incorporated into a large number of population-based studies. Dried blood spots were originally developed in the 1960s for neonatal screening programs, and over the past 20 years they have been increasingly used to facilitate blood collection for research purposes in diverse community-based settings. Sample collection is relatively straightforward, and can be implemented in field settings by nonmedical interviewers. Once collected, samples are allowed to dry and can be stacked for storage and shipment, and most biomarkers remain stable for days, if not weeks, at room temperature. The logistics, burdens, and costs of sample collection and transport are greatly reduced in comparison with venipuncture, lowering the barriers to blood collection in large-scale studies. Protocols for over 100 biomarkers have been validated for use with dried blood spots, including important indicators of endocrine, immune, reproductive, and metabolic function, as well as measures of nutritional status and infectious disease (McDade et al., 2007).

Finger-stick blood sampling can also be used for the onsite analysis of biomarkers with small, portable 'point-of-care' devices. As with blood spot sampling, a sterile lancet is used to collect blood from the finger, and a drop of blood is placed into a cartridge or cuvette that is then inserted into the instrument. Results are available seconds or minutes later. Hemoglobin has been widely measured using this approach, and point-of-care devices have also been developed for the measurement of glucose, HbA1c, C-reactive protein (CRP), lipids, blood chemistry, or liver function. A single finger prick can be used to provide capillary whole blood for onsite analysis, as well as for collection on filter paper for subsequent analysis in the laboratory.

Saliva is an attractive alternative to blood sampling since collection is noninvasive, participants can collect samples by themselves during their normal daily routines, and repeat sampling is possible. For these reasons saliva sampling has

been successfully implemented in a large number of experimental, naturalistic, and population-based studies (Adam and Kumari, 2009). However, salivary biomarkers are typically of interest only if they represent circulating concentrations in blood, and the number of biomarkers for which this is the case is limited. Cortisol – a steroid hormone that is centrally involved in the body's response to stress – can be quantified in saliva and is the focus of studies investigating biological stress responses in relation to contextual factors and downstream health outcomes. Methods for measuring aspects of reproductive function, immune function, infectious disease, and drug use have also used saliva.

As with saliva, many biomarkers that otherwise require blood can be measured in urine samples. Urine collection has been successfully implemented in population-based studies with younger and older participants, men and women, and in a variety of cultural settings. While sample collection is relatively straightforward, many biomarkers require urine samples to be refrigerated for frozen soon after collection and during transport to the lab. Urine samples can be analyzed for biomarkers of renal function, stress hormone activity, reproductive hormones, sexually transmitted infections, toxic substances, and drug metabolites.

Analyzing cortisol in hair samples has emerged as an alternative to saliva and urine, with the benefit of providing a retrospective measure of cortisol exposure (Sauve et al., 2007; Kirschbaum et al., 2009). Human hair grows approximately 1 cm per month, and samples close to head represent a cumulative record of recent exposure. More distal samples provide information on exposures up to several months earlier. For many research purposes such an integrated measure of cortisol may be appropriate, although a disadvantage of this approach is that it cannot capture aspects of diurnal cortisol rhythms (e.g., cortisol awakening response, slope of decline across the day) that have been shown to provide valuable information in addition to overall cortisol level (Adam and Kumari, 2009).

Recent Applications of Biomarkers in Population-Based Surveys

The number of sociodemographic studies incorporating biological measures has grown rapidly, in large part due to methodological innovations that have reduced the burdens and costs associated with biomarker data collection. A comprehensive review of these studies is well beyond the scope of this article, but a handful of studies are highlighted to demonstrate the range of applications and their potential to advance scientific understandings of the dynamic relationships among society, biology, and health. In addition to their scientific contributions, studies such as these are excellent sources of information on how to collect biomarker data since their protocols are often publicly available.

National Health and Nutrition Examination Survey

Since the 1960s, the National Center of Health Statistics has implemented the National Health and Nutrition Examination Survey (NHANES), representing a major series of community-based studies designed to evaluate the health and nutritional status of adults and children in the United States (http://www.cdc.gov/nchs/nhanes.htm). Since 1999 NHANES has become a continuous research program that includes a nationally representative sample of about 5000 people every year, with changes in specific health and nutrition measures across surveys depending on emerging issues in population health.

Interviews to collect demographic, socioeconomic, and self-reported health information are conducted in participants' homes. Physical exams and biological specimen collection are implemented using specially designed mobile examination centers that travel to selected research locations around the country. By bringing these centers into community locations NHANES is able to collect an impressive set of biological measures that have clinical as well as public health significance. Recent surveys have collected whole blood, plasma, serum, urine, hair, DNA, saliva, and nasal and vaginal swabs, and have implemented laboratory analyses for measures of micro- and macronutritional status, cardiometabolic function, reproductive function, infectious disease, and exposure to environmental contaminants.

Given the size, scope, and national representation of NHANES, data are often used to determine the prevalence of risk factors and major diseases across sociodemographic groups in the US, and to inform policy accordingly. The study is widely regarded as the gold standard for assessing health in community-based settings, and findings are applied as benchmark comparisons for clinical, epidemiological, and demographic studies collecting overlapping measures. NHANES does not include a comprehensive panel of psychosocial or contextual measures, and the serial cross-section research design precludes longitudinal, within-person analyses of change over time. Nonetheless, the in-depth measurement of a wide range biomarkers in a large representative sample is a major strength, and the data make important contributions to demographic research on population health in the US.

The Health and Retirement Study

The Health and Retirement Study (HRS) is a nationally representative, longitudinal study of aging in the US that was launched in 1992. The original sample consisted of 12 652 individuals born between 1931 and 1941, and the study now includes more than 26 000 Americans over the age of 50 years (http://hrsonline.isr.umich.edu/). Surveys are implemented every 2 years, and focus on physical and mental health, cognitive functioning, financial and employment status, retirement planning, social/family environments, health care access and usage, and insurance coverage.

The HRS first collected dried blood spots in 2003 from a subsample of participants, for the measurement of HbA1c. In 2006, a larger panel of measures was collected during face-to-face interviews with a random one-half of the sample, followed by the other half of the sample in 2008. Samples and measures included dried blood spots, saliva for DNA, blood pressure, anthropometrics (height, weight, waist circumference), and a series of physical performance tests (e.g., grip strength, balance, peak flow, timed walk). Blood samples were

analyzed for HbA1c, total cholesterol, high-density lipoprotein cholesterol, CRP, and cystatin C. The collection of biomarker data is also part of the 2010 and 2012 surveys.

Health is a defining feature of the HRS, and in many ways it reflects – and has helped define – a new generation of population-based, social science surveys that include objective biological measures in addition to more commonly used self-report measures (Weir, 2007). Studies of aging and health in particular have been important in advancing integrative biosocial survey research (Seeman and Crimmins, 2001), and the HRS experience has encouraged parallel studies of aging in several countries in Europe and Asia to harmonize data collection efforts to enhance comparability.

National Longitudinal Study of Adolescent Health

The National Longitudinal Study of Adolescent Health (Add Health) is a longitudinal study of the social, behavioral, and biological linkages defining trajectories of health from adolescence to adulthood in the US (Harris, 2011). Wave 1 was conducted in 1994–95 with a nationally representative sample of 20 745 adolescents in grades 7–12, with follow-up surveys in 1996, 2001–02, and 2007–08. In-home interviews collect information on self-reported health and health behaviors, access to health care, peer and family contexts, psychosocial stressors and mental health, educational aspirations and attainments, employment experience, socioeconomic resources, and romantic relationships. The study also includes information from a parental interview at wave 1, neighborhood and school information from administrative sources, and peer/friendship network data. A strategic oversample of identical and fraternal twins, biological siblings, and nonrelated siblings is an innovative feature of the dataset that allows for analyses investigating genetic and contextual influences on health outcomes.

Initially, Add Health included only self-reported and parent-reported health information. Wave 3 introduced the collection of saliva and urine for HIV and sexually transmitted infection testing, and for DNA genotyping of candidate polymorphisms in the genetic subsample. Biomarker collection was expanded during wave 4 to cover a wider range of measures relevant to health in young adulthood. Anthropometric measures included height, weight, and waist circumference, blood pressure was recorded, and dried blood spots were collected and subsequently analyzed for cardiometabolic (total cholesterol, high-density lipoprotein, HbA1c, glucose) and immune (CRP, Epstein–Barr virus antibodies) function. All participants were also asked to provide buccal cell samples for DNA genotyping. Biomarker collection protocols were implemented in the home as part of the wave 4 interview.

The Add Health study has the potential to make important contributions to population health due to its large, nationally representative sample, the collection of longitudinal data that includes a wide range of measures of social contextual factors during important periods of development, and the integration of biological measures that represent the function of key physiological systems. In addition, the study is unique in focusing on the transition to young adulthood, which is a time when the cohort is settling into new work, family, and social roles that matter to health, and a time when predisease pathways can be measured to gain insight into how these contexts may influence future disease risk.

Moving to Opportunity

In addition to adding objective information on health and biological function in observational studies, biomarkers provide unique opportunities to evaluate the impact of policy-relevant social experiments. The Moving to Opportunity (MTO) demonstration project represents an example of this type of application. The study was initiated in 1994 with the goal of understanding how residential contexts influence employment opportunities, educational attainments, income, and general well-being. The focus of MTO was on families in Baltimore, Boston, Chicago, Los Angeles, and New York living in the most impoverished urban neighborhoods. Families with children in public housing were randomly assigned to one of three groups: (1) rent subsidy vouchers that could only be used if the family moved to a low-poverty neighborhood; (2) traditional vouchers with no restrictions on residence; and (3) a control group that was not offered new assistance.

In 2008–10, 10–15 years after randomization, participants were followed up to assess the long-term impacts of the intervention on health, as well as other outcomes. The panel of biological measures included height, weight, waist circumference, and blood pressure, as well as dried blood spot samples for the analysis of HbA1c, CRP, Epstein–Barr virus antibodies, total cholesterol, and high-density lipoprotein. Intention-to-treat analyses indicate that assignment to the low-poverty voucher group resulted in a 13–19% reduction in obesity in comparison with the control group, and a 22% relative reduction in diabetes, as defined by HbA1c greater than 6.5% (Ludwig et al., 2011).

The magnitude of these effects is large, and the experimental study design increases confidence in concluding that they are indeed causal. The inclusion of biomarkers in social experiments identifies the specific biological pathways and health outcomes that are affected by contextual factors like neighborhood poverty, which may inform future interventions. In addition, biological measures can provide more objective outcome measures since subjective health measures are vulnerable to biased reporting that is associated with assignment to particular experimental groups. Lastly, implementation of biological outcome data may be particularly effective in mobilizing the attention of policy makers and informing interventions around important social issues.

Study on Global AGEing and Adult Health

Biological measures have been successfully implemented into population surveys all around the world, and in fact, many of the 'field-friendly' biomarker methods that are now being integrated into demographic studies in the US were originally developed to meet the challenges of data collection in remote community-based settings (Campbell, 1994; Worthman and Stallings, 1997; Ellison, 1988). Anthropometric measures like height and weight have been central parts of global surveillance efforts to identify undernutrition, particularly in childhood (World Health Organization, 1995; Gibson, 2005), while the ongoing Demographic and Health

Surveys (http://www.measuredhs.com/) are increasingly turning to the collection of biological specimens to detect micronutrient deficiencies and infectious diseases. Biological measures in lower-income nations tend to focus on outcomes related to undernutrition and infectious disease, but rising rates of overweight/obesity globally – even in the context of undernutrition and high burdens of infectious disease (Boutayeb, 2006) – are expanding the range of biomarkers that are relevant in international research.

The Study on Global AGEing and Adult Health, (SAGE) led by the World Health Organization, represents an ambitious cross-national data collection effort that will provide useful comparative data for demographic studies of health in the US (http://www.who.int/healthinfo/sage/cohorts/en/index.html). A baseline cohort of more than 60 000 adults age 18 years and older was established in 2002–04, with nationally representative samples of participants in six countries: China, Ghana, India, Mexico, Russia, and South Africa. Wave 1 was implemented in 2007–10, and included self-reported measures of health, as well as a series of tests of physical performance (timed walk, spirometry, vision, grip strength), cognitive function, blood pressure, anthropometric measures, and dried blood spot samples. Follow-up surveys are planned for 2013 and 2015.

Biomarkers can provide practical information for surveillance efforts and public health interventions in under-resourced lower-income nations. For research purposes, comparisons across populations living in diverse social, cultural, and ecological settings are powerful tools for generating hypotheses regarding the role of contextual factors in shaping human physiological function and health. Developmental plasticity and ecological sensitivity are defining characteristics of human biology, and as a result, global environmental variation produces substantial variation in human biology around the world (Stinson et al., 2012). Health research conducted exclusively in affluent industrialized settings like the US cannot capture the full range of socioecological environments that may be important for gaining insights into the development and function of critical physiological systems. A field-based, comparative approach to research on human biology in diverse communities around the world therefore has the potential to advance our understanding of human biological variation, with implications for understanding health in the US and internationally (McDade, 2012).

Conclusion

The future is bright for research that integrates conceptual and methodological tools from the biomedical and social/behavioral sciences. Demography provides a solid foundation for modeling patterns of fertility, morbidity, and mortality over the life course in diverse populations around the world. A new generation of research is taking advantage of methodological innovations that facilitate the direct, objective measurement of biological processes in naturalistic settings, greatly expanding the range of possibilities for future research. By moving beyond vital records and self-reported measures, this research has the potential to have an immediate impact on demography, and to answer the call for more integrative, transdisciplinary approaches to population health (Weinstein et al., 2008). In the long run, this approach will transform the study of human development, biology, and health in relation to the diverse social and physical contexts within which human lives are embedded.

Abstract

The biomedical sciences have become a prominent site of the production of knowledge about health, disease, and behavior. Here, we provide an overview of the genealogy of the concept of biomedicine, the philosophical and methodological assumptions upon which it came to rest, an overview of the growing scholarship in the history and sociology of biomedicine, and a vision of some future directions for scholarship.

Introduction

The History and Sociology of the Biomedical Sciences (HSBS) might seem to be a logical point of overlap between the history of biology and medicine. However, in the recent past, historiographic trends conspired to divert the attention of both these fields from their common ground. During the 1980s and 1990s many historians of medicine turned away from accounts focusing on great ideas and heroic doctors. Instead, they emphasized the social and ideological facets of medicine, especially through a close focus on the experiences and agency of patients, a 'history from below.' While salutary in many respects, this 'social turn' left out the production of biomedical knowledge in the clinic as well as the laboratory (Cambrosio and Keating, 2001). Historians of biology, meanwhile, generally directed their attention toward the development of experimental, especially molecular, knowledge in the laboratory, taking for granted its 'application' in the clinic (de Chadarevian and Kamminga, 1998).

Since the 1990s, HSBS diverged from these trends in seeking to understand the practices and knowledge produced at the intersection of the laboratory and clinic, but until recently this area of scholarship has been a patchwork rather than a field. The years since the first edition of this encyclopedia have been fruitful for studies of HSBS (Strasser, 2014). The emphasis on practice in HSBS has produced many studies whose narratives unite the laboratory and clinic, demonstrating the entangled relationship of laboratory and clinical practice well as the links between both of these sites and society as a whole (Creager, 2002; de Chadarevian, 2002; Gaudillière, 2002; Keating and Cambrosio, 2003; Landecker, 2007; Lindee, 2005; Löwy, 2010; Rader, 2004; Wailoo and Pemberton, 2006). As Ilana Löwy (2011) recently argued, "biomedicine studies" promise to develop conceptual tools capable of integrating the social, cultural, and material accounts of practice, explore the definition of normal and pathological bodies, and understand the role of sites such as the clinic and activities such as computation in the production of knowledge about health and disease.

Defining Biomedicine

Genealogy of the Term

Biomedicine as a term first arose in the early twentieth century. The terms 'biomedicine' (and 'biomedical') have different origins and trajectories in English, German ('Biomedizin'), and French ('biomédecine'), but very similar meanings today. 'Biomedical' first appeared in the writing of American and British authors in the 1920s, and was followed a decade later by 'biomedicine' (or 'bio-medicine') (Keating and Cambrosio, 2003: Chapter 3). From the onset, biomedicine and biomedical research referred to a kind of medicine that was closely associated with experimentation and the laboratory rather than the experience of physicians and the clinic. The American Illustrated Medical Dictionary defined biomedicine as "clinical medicine based on the principles of physiology and biochemistry" rather than the expertise physicians gained through clinical observation (Dorland, 1923: 172).

After the Second World War, biomedicine increasingly came to signify 'modern medicine' based on the expertise of the laboratory as opposed to 'traditional medicine' associated with the clinical experience and acumen of individual physicians. Although the laboratory had served as a rallying standard for medical reformers since the late nineteenth century, it was only after 1945 that laboratory-based medicine, identified with biomedicine, began to have a strong impact on clinical practice (Warner, 1991; Cunningham and Williams, 1992; Quirke and Gaudillière, 2008). As biomedicine grew socially and politically to a dominant practice, it became associated with 'orthodox medicine' (opposed to 'alternative medicine'), 'scientific medicine' (opposed to 'clinical' or 'traditional medicine'), and 'Western medicine' (opposed to 'non-Western' or 'indigenous medicine'). A key assumption of biomedicine, to which we will return, is that the difference between the normal and the pathological is one of degree, not of kind. This in itself represents a relatively recent development in the history of medicine and a key point of entry for biomedical approaches to disease.

Philosophical Themes

The study of health and disease in the laboratory draws upon a number of implicit and explicit philosophical assumptions. Chief among these is 'reductionism,' held to be a critical tenet of biology in opposition to more holistic clinical approaches. Reductionism consists of at least three distinct claims. First, an ontological claim that a whole organism is 'nothing more' than the sum of its parts; second, an epistemological claim that the organism is best explained by reference to its parts; and finally a methodological claim that the organism is best investigated

by the study of its parts (Sarkar, 1998). The reductionist position is in opposition to various 'holistic' interpretations of disease, which encompass a range of positions from nineteenth century Romanticism to twenty-first century systems biology and ecology (Lawrence and Weisz, 1998; Rosenberg, 2007: Chapter 8). In discussions of biomedicine, many of these claims have been associated with the rise of molecular approaches to biology and medicine after 1945 (Morange, 2000). However, this recent wave of 'molecularization' is only one episode in a longer history of reductionist approaches to biology (de Chadarevian and Kamminga, 1998).

Modeling is another key assumption of biomedical research closely associated with reductionism. The use of models or exemplars is found in both medicine and biology. In medicine, physicians often use exemplary clinical case descriptions for understanding particular illnesses (Anderson, 2013). In biology, researchers focus on model organisms or *in vitro* model systems because they believe in the universality of living processes. From the assumption that similar processes in different organisms operate by the same biological mechanisms, as claimed by the nineteenth century French physiologist Claude Bernard, experiments aiming to elucidate a particular process in humans may be carried out using organisms or systems which are better suited to laboratory conditions. (Prominent model organisms are mice, flies, worms, yeasts, bacteria, and viruses. See Endersby (2007).) Although they are the product of human artifice, these systems are held to be 'model systems' or 'model organisms' which are capable of standing in or substituting for more complex phenomena (Rheinberger, 1999). As the molecular biologists Jacques Monod and François Jacob famously put it in 1961, "[What is] true of *E. coli* must also be true of Elephants" (Morange, 2000). These modeling practices have been immensely powerful for biological research and its applications to human diseases. The use of model organisms has become a dominant practice in biomedical research in the twentieth century (Creager et al., 2007).

Biomedicine: Grounded in Laboratory Science?

Although there is no universally agreed upon definition of 'biomedicine,' it is often conceptualized as the search for therapeutic innovations in the laboratory. In the early nineteenth century physicians such as German pathologist Rudolf Virchow had grounded the autonomy of medicine on the 'ontological' presumption that disease was caused by processes distinct from those taking place in the healthy body, but in the late nineteenth century, other physicians started to challenge this view (Temkin, 1977). Most notoriously, Claude Bernard advocated a 'physiological view' of disease, where pathology was a gradual deviation from normal biological processes. Medicine could thus be studied as a subset of physiology and other sciences. As he asserted in his Introduction to Experimental Medicine (1865) "for a man of science, there is no separate science of medicine or physiology, there is only a science of life…the true sanctuary of scientific medicine is the laboratory…every scientific physician should have, therefore, a physiology laboratory" (Bernard, 1957: 146–147). Even if Bernard's vision proved difficult to realize in practice, the study of 'normal' and 'pathological' states could both be pursued by the same laboratory-based means (Canguilhem, 1978). The pursuit of therapeutic aims in the laboratory received further support later in the nineteenth century from Louis Pasteur's and Robert Koch's innovations in bacterial culture and the rise of microbiological theories of disease etiology (Geison, 1995; Gradmann, 2009).

Under this understanding of biomedicine, laboratory research on basic biological mechanisms in almost any organism has potential medical relevance. This argument has been enthusiastically championed by molecular biologists since the mid-twentieth century. However, as historian of science Jean-Paul Gaudillière (2002) has shown, many of these laboratory researchers sought to distance themselves from the practices of clinical research even while claiming that they were contributing to it through their inquiries into the 'basic' or 'fundamental' process of life. The limitations of the distinction between 'basic' (laboratory) research and 'applied' (clinical) practice are immediately apparent in the case of biomedicine. Indeed, the production of knowledge about therapeutics always requires a clinical phase involving patients, where research and therapy take place at the same time on the same subjects (Löwy, 1996). We return to the epistemic questions raised by this observation below.

Biomedicine as Practice

Diagnosis and Etiology

Early work on biomedical practices sought to integrate biomedicine into the framework of a narrow range of laboratory practices rather than examining its diversity. More recent scholarship on biomedical research into the diagnosis and etiology of disease has questioned this assumption by following particular practices to open up our understanding of how biomedical knowledge is produced. By following the flow of materials and information between laboratory and clinic, for example, Keating and Cambrosio have suggested that biomedicine rests upon the construction of 'platforms' capable of coordinating the action in the laboratory with the clinic rather than the one-way application of laboratory studies to therapeutics. For example, the diagnosis of lymphoma through the development of immunological tests in the 1990s did not displace morphological analysis of bone marrow samples. Instead, teams of oncologists, technicians, and immunologists seeking to make a diagnosis had to consider the evidence from many forms of practice (Keating and Cambrosio, 2003: 4–7, 50–56).

The single most prominent feature of contemporary biomedical diagnosis is the increasing power attributed to genes. From cancer to political leaning and sex drive to criminality, genes have been invoked to explain a growing number of traits (Nelkin, 2004). However, the identification of genetic factors involved in the etiology of hereditary disease has often relied not only on molecular biology but also on long-term clinical observation, popular knowledge of heredity, and family histories. The history and experience of individual populations, such as the Pennsylvania Amish or Ashkenazi Jews, are a vital part of the production of genetic and genomic knowledge in the laboratory (Comfort, 2012; Gibbon et al., 2014; Lindee, 2005; Wailoo and Pemberton, 2006).

These practices have progressively blurred the boundaries between the normal and pathological and between health and illness. Disease, once defined by qualitative symptoms, is now more often defined in terms of quantitative metrics. For example, the diagnosis of cardiovascular disease or cancer has been transformed from distinct moments of illness into lifelong risks for healthy individuals, defined by ranges of 'normal' values for biomedical markers (tension, cholesterol, genes, antigens, etc.) rather than observable symptoms (Aronowitz, 1998; Greene, 2007).

Clinical Trials

Recent scholarship suggests that clinical research has been no less important as a site for the development of biomedical knowledge about disease. The single most important event in integrating hospitals and patients into the biomedical enterprise was the development of the randomized clinical trial (RCT) after the Second World War (Marks, 1997). Before the RCT, questions of drug safety and therapeutic efficacy were mainly adjudicated through the observation of patients by a relatively small number of experienced physicians. The efficacy of a particular treatment rested on the professional credibility of the physicians involved rather than on a standardized method. The adoption of statistical methods promised to provide an 'objective' means of carrying out these evaluations. When state agencies such as the US Food and Drug Administration started to take a more active role in regulating the drug market, they also promoted the widespread use of RCT as the primary standard for determining safety and efficacy (Carpenter, 2010; Daemmrich, 2004).

Advocates of RCT and some historians have assumed that the development of RCT provided an important basis for testing of the efficacy for human subjects of compounds developed in laboratory settings. However, it appears equally true that RCTs were an important site for the production of knowledge about diseases themselves. Ilana Löwy has shown that clinical trials in hospitals are no less effective in producing knowledge about the workings of diseases and their possible treatments than experiments in laboratories (Löwy, 1996). Other recent scholarship has argued that RCTs also produced knowledge about diseases themselves. In this view, clinical trials contribute to the production of biomedical knowledge and are the preferred site for defining and demonstrating the relationship between therapeutic agents and diseases. Moreover, scale and organization also played a vital role in the production of such knowledge. With thousands and sometimes tens of thousands of participants, RCTs during the 1970s and 1980s started to produce their own classifications of disease, such as types of breast cancer based on trial results rather than laboratory diagnostics (Keating and Cambrosio, 2012). This means that clinical trials may yield new definitions of diseases and target populations as well as more conventional verdicts on efficacy.

Risk and Enhancement

Biomedicine has blurred the boundary between the restoration of health and the enhancement of individuals. New methods of diagnosis have profoundly affected the mission of medicine and our understanding of what disease is. Rather than restoring health, biomedical treatments offer ways to improve an individual's physical and mental performance in an endless "pursuit of perfection" (Rothman and Rothman, 2003). Hormone replacement therapy, for example, started off as therapy for some of the most severe symptoms of menopause (which itself can hardly be characterized as a 'disease'), only to become a preferred treatment to keep the skin of postmenopausal women supple (Watkins, 2007). Enhancement and pharmaceutical marketing have intersected with the development of 'risk' interpretations of disease. Originating in the focus of public health on disease incidence in aggregate populations, the risk notion of disease has become integrated into biomedical discourse as a key concept through which individual patients understand their health or illness (Rothstein, 2003). By shifting its aim from the elimination of disease to the management of disease risks, biomedicine has opened the door to understanding health as the continuous pursuit of risk reduction (Aronowitz, 1998; Jones, 2013).

Biomedicine and Society: The Biomedical Complex

In addition to studies of practice, the HSBS has produced a body of work seeking to understand biomedicine's political, institutional, and social development. Scholarship here has focused on tensions arising from the sponsorship of laboratory biology by organizations with a commitment to public health rather than the creation of biological knowledge for its own sake. While originally consisting of universities and private foundations, the range of actors involved in the patronage of biomedical research expanded over the course of the twentieth century to include state public health authorities, patient advocacy groups, and various industries. Reconciling the actual activities of biomedical researchers with the aspirations of their patrons marks an ongoing process, one that yields rich material for studies of biomedicine's social relations in many contexts.

Biomedicine, Philanthropy, and the State

Philanthropic initiatives played a critical role in developing the intellectual and institutional agendas of biomedicine. At the beginning of the twentieth century, biomedicine's emphasis on laboratory research, especially biological research, accorded universities a central role in its development. National governments, by and large, gave modest support to biological and medical research. These early conditions amplified the influence of philanthropies, the one set of organizations that actively sought to support and develop biomedical research in the early twentieth century. Private foundations such as the Carnegie Institute of Washington or the Rockefeller Foundation supported the application of the biological sciences to understanding human health (Kohler, 1991). These foundations were able to exert considerable influence over the direction of biomedical research as a field, although the extent to which their influence altered the research agendas of individual scientists is still a matter of debate among historians. The Rockefeller Foundation, for example, supported a number of research projects, such as the physical chemist Linus Pauling's

study of the molecular basis of biological processes (which formed the basis of his later work on sickle-cell anaemia) hoping to create a new 'science of man' and possibly bring eugenics on a sound scientific basis (Kay, 1993). (For the view that Foundations played a major role, see Kay (1993); for the view that Foundations did not, see Abir-Am (2002).)

These foundations aimed at a better understanding of the biological basis of heath, disease, and behavior, but declined to support more 'holistic' approaches. Critically, philanthropic activity strongly supported the early rise of molecular biology at a time when its approaches fell outside traditional academic disciplines; this rise subsequently played a leading role in shaping biomedicine as a laboratory science. Just after the Second World War, the Rockefeller Foundation played a key role in supporting the reconstruction of European science by encouraging the mobility of researchers, the organization of international conferences, and crucially, the purchase of expensive scientific instruments for biomedical research (Gemelli et al., 1999).

After the Second World War, state patronage for academic research vastly expanded. Although not as expensive as 'big science' projects in physics or astronomy, the biomedical sciences were indebted to this patronage for their expansion. However, this patronage was not for science on its own terms. Health and medicine, like national security, emerged as areas where the state was expected to cultivate and guard the safety of its citizens. In the United States and Europe, in practice this meant providing support to university-based biological research (Appel, 2000; Quirke and Gaudillière, 2008; Wright, 1994: Chapter 1). Funding for research accordingly tended to focus on diseases rather than disciplines, as exemplified by the disease specific Institute structure of the US National Institutes of Health or initiatives such as the 'War on Cancer' of the 1970s (Patterson, 1987; Mukherjee, 2011). In some cases, such support benefited research on particular model organisms, such as mice, or the creation and promotion of particular methods for the study of biological processes, such as radioisotopes. This state patronage played a decisive role in the production of biomedical knowledge (Creager, 2013; Fujimura, 1996; Rader, 2004).

Patient/Disease Advocacy

The early historiography of biomedicine often regarded patients as passive objects of biomedical expertise. However, the growth of contemporary disease advocacy movements has encouraged scholarship addressing patients as active subjects in the production of biomedical knowledge. Following the model of public philanthropy, patient organizations have played an especially important role in this regard, influencing science policy and research agendas and providing substantial financial support for biomedical research on specific diseases. Most famously, the National Foundation for Infantile Paralysis, founded in 1938, raised money from the American public to support polio research, leading to the Salk vaccine in 1955 (Oshinsky, 2005). During the 1970s, the American Cancer Society played a dominant role as an advocate for the 'War on Cancer.' In the 1980s and 1990s, the fundraising telethons of the Association Française Contre les Myopathies supported the study of the genetic basis of muscular dystrophy, leading to the identification of the first gene related to Duchenne muscular dystrophy (Rabinow, 1999; Rabeharisoa and Callon, 2002). A significant shift in the orientation of patient organizations toward biomedical research occurred with the onset of the AIDS epidemic. As the sociologist Steven Epstein has shown, patient organizations such as the AIDS Coalition to Unleash Power (ACT UP) not only provided financial support for scientific research on AIDS, but also claimed a form of 'lay expertise' that contributed to the production of scientific knowledge about the disease (Epstein, 1996).

Biomedicalization

The development of the biomedical sciences has also been entangled with the expanding scope of medical authority. This is the latest episode in what scholars have referred to as the progressive 'medicalization' of society since the nineteenth century (Conrad, 2007). The concept of medicalization has recently been extended by scholars to the concept of 'biomedicalization,' a specific kind of medical transformation. Biomedicalization emphasizes technological and scientific intervention, based less on the 'clinical gaze' than the 'molecular gaze,' as well as the creation of new individual and collective identities ('biosocialities') grounded upon shared biomedical traits such as risk factors or disease genes (Clarke et al., 2010; Burri and Dumit, 2007; Rabinow, 1996; Rose, 2007; Lynch et al., 2010). These new etiologies and identities of diseases occupy contentious social ground because they suggest ways to diagnose and treat particular diseases while sidelining others. In particular, critics charge that genetic causes or predispositions have been granted exclusive status in these explanations, to the detriment of explanations examining the social, economic, environmental, or behavioral determinants of health (Krimsky and Gruber, 2013). Debates surrounding the causation of conditions such as obesity, autism, or fatigue continue to offer numerous further opportunities for tracing the process of biomedicalization.

Biomedicine and Political Economy

The biomedical sciences have been deeply shaped by the intellectual property regimes concerning drugs and biological materials. In Europe, and especially in France, drugs were originally excluded from the protections of intellectual property law because of their importance for human health. However, after the Second World War, the United Kingdom (1949), France (1959), and Germany (1965), for example, passed legislation authorizing the patenting of therapeutic substances (Gaudillière, 2008). According to historian of science Jean-Paul Gaudillière (2002), such legislation should be understood as part of post-war efforts by states to modernize by fostering scientific research in service of economic growth.

The extension of patent protection played a particularly significant role in stimulating the rise of the biotechnology industry in which new and experimental therapeutic technologies were based, not on chemical synthesis or extraction, but on the production of substances through genetically modified organisms. Although the focus on the therapeutic possibilities

of 'biological' substances was far from novel (von Schwerin et al., 2013), following the development of recombinant DNA technology between 1972 and 1974, it became theoretically possible to produce almost any protein in unlimited quantities with high purity once a corresponding gene had been isolated. The production of insulin and other therapeutically useful proteins was envisioned as a major market for the application of recombinant DNA technologies by biotechnology startups. The expansion of the biotechnology industry accelerated after the 1980 US Supreme Court decision in Diamond versus Chakrabarty established that a "live, human-made micro-organism is patentable subject matter." In 1988, the US Patent and Trademark Office extended this decision to include transgenic mammals, approving a patent filed by Harvard University for 'OncoMouse,' a mouse specifically modified to serve as a model organism for cancer research (Kevles, 1994).

This ruling, coupled with the greater ease of patenting state-supported research fostered by the Bayh-Dole Act in 1980, promoted a close relationship between the pharmaceutical industry and academic research in the United States. The pressure to produce economically valuable research has subsequently been criticized for distorting the research priorities of universities and scientists. The rhythm of biomedical discovery, for example, has become profoundly entangled with the promissory environment of financial markets (Hughes, 2011; Rajan, 2006). The impact of these policies on the direction of biomedical research marks an exciting area for the future study of biomedical practices and institutions within the history of innovation and intellectual property.

Future Opportunities for Scholarship

While the completion of the Human Genome Project in 2003 seemed to show that molecular biology had realized its ambition of providing explanations of health and disease in terms of discrete 'master molecules,' subsequent experience has suggested that the process is far more complicated (Reardon, 2005; Keller, 2010; Paul, 1998). The contemporary relationship between biology and medicine remains unsettled; a circumstance that offers rich ground for the further growth of scholarship in HSBS, particularly lines of work that overlap with disciplines such as anthropology in efforts to examine contemporary historical events (Lock and Nguyen, 2010). Following the practices of biomedicine beyond the axis of laboratory and clinic into society offers many opportunities for study by the social and behavioral sciences. In closing, we will suggest a few of these areas.

The emphasis in this article on the United States and Western Europe evident reflects the scope of scholarship in HSBS. Analyzing the development of biomedicine as a global phenomenon offers many opportunities. Most RCT for drug development, for example, now occur in developing rather than industrial countries (Petryna, 2009). Indeed, the global dimension of clinical trials cannot be regarded as a recent development, as it has been a longstanding feature of cancer research (Keating and Cambrosio, 2012). Biomedical definitions of disease often appear very different when they are examined in distinct populations or localities. For example, the biomedical idea that sickle-cell anemia is a 'molecular' disease has been complicated by examining how this genetic discourse was received by Senegalese patients suffering from the disease and their physicians (Fullwiley, 2011).

Tracing the circulation of materials – from chemicals to tissues – has provided a powerful tool for analyzing the practices and social relations of biomedicine. Following the history of individual drugs from the laboratory to market has been used successfully by a number of recent studies (Bud, 2007; Goodman and Walsh, 2001; Pieters, 2005; Rasmussen, 2008; von Schwerin et al., 2013; Watkins, 2007). In following these substances, these studies manage to integrate a number of the perspectives on laboratory, clinic, and society in biomedicine discussed above, especially through the state regulation of therapeutic substances (Carpenter, 2010; Gaudillière and Hess, 2012; Gradmann and Simon, 2010; Greene and Watkins, 2012). Research that follows the movement of materials has also suggested that the individual body is not always the appropriate scale for understanding the production, reception, or uses of biomedical knowledge. This insight opens ground for the fruitful collaboration between HSBS and environmental studies, to gain insight into how the causation of disease is understood in relationship to ecological and economic change from the study of areas as diverse as allergy, pollution, food additives, agriculture, or occupational safety (Mitman, 2007; Langston, 2010).

The changing scale of biomedical research, the means developed to create and process growing amounts of biological data ('big data biology'), and the increasing integration of biological and medical information offer numerous opportunities for further study. The role of computers in biomedical work, for example, has only recently started to receive historical attention, despite the ubiquity of information technology in current biomedical research (November, 2012; Stevens, 2013). The deep continuities between current modes of collecting, comparing, and computing data and earlier scientific practices, in natural history and the clinic for example, have also just begun to be explored (Strasser, 2012).

Finally, the relationship between neoliberalism and the biomedical sciences appears to be closely linked with the process of biomedicalization (Clarke et al., 2010; Cooper, 2008; Rajan, 2006). The development of lay expertise has gone hand in hand with the development of consumer markets for biomedical knowledge. Before the Food and Drug Administration restricted the disclosure of genetic information in 2013, direct-to-consumer companies such as 23andMe offered cheep genetic testing and broad promises for a "personalized medicine" (Prainsack and Vayena, 2013). How much this promise will hold true, and the extent to which it represents a departure from the universalist ideal that has been so important for the construction of biomedicine offer rich terrain for further study.

Biosocial Approaches: Crime

Michelle A Coyne and John P Wright, University of Cincinnati, Cincinnati, OH, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Over the past two decades, scholars have discovered a host of information regarding genes, brain activity, and other biological processes. Many of these biological discoveries are related to behavior. Biosocial approaches to crime examine the way that biological factors such as genes and the brain affect environmental factors and influence criminality over the life course. This article provides an overview of the evolution, main approaches, and contributions of biosocial criminology to linking the way that both nature and nurture influence criminality.

Introduction

The biosocial approach to understanding crime is relatively new, emerging only recently as a prominent and respected area of research. The rapid ascendancy of biosocial criminology owes much of its recognition to the sheer volume of evidence biosocial scholars have produced. Using a variety of genetically informed research designs, including twin studies, biosocial criminologists have produced a broad array of evidence that reveals and implicates the complex interplay between 'nature,' those biological and genetic factors that influence human development and behavior, and 'nurture,' often defined as our experiences with certain social variables, in the development of criminal behavior. The evidence linking biological factors to crime is now extensive. However, one of the major insights garnered from the biosocial approach is that criminal behavior is often produced when biological factors and social factors interlock – that is, when they correlate and when they interact. Today, findings from the biosocial approach are now being used to develop more effective treatments for criminal behavior, and they are gaining a broader audience of scholars.

Although biosocial criminology has only recently penetrated mainstream criminological thinking, the roots of biosocial criminology extend to Darwin's writings on human origins and evolution and to Gregor Mendel's discovery of molecular genetics. Interestingly, Darwin and Mendel each understood that many traits and behaviors were produced by environmental and biological factors. Even so, the road that led to the emergence of biosocial criminology has been long and perilous – ending the careers of earlier scholars who dared to breach the wall of imposed disciplinary ignorance that would eventually make the biological study of human behavior, especially criminal behavior, taboo. Indeed, few areas in the social sciences have been subject to as much conflict, prejudice, and political ideology as has been the connection of biology to behavior. For reasons that had little to do with science, contemporary biosocial criminology almost did not emerge and, consequently, the insights provided by biosocial scholars almost did not appear. Despite the recent ascendancy and acceptance of the paradigm, it remains perched perilously close to intellectual obscurity. In the following pages, we thus trace the journey of biosocial criminology, from its early emergence in criminology, through the history of its discrimination, to its recent revitalization, and finally to what it offers the future of criminology and the social sciences.

The Evolution of the Biosocial Approach

Biological explanations of crime predate sociological explanations of crime and at one time were the dominant approach to examining and understanding criminality. From its inception, the biological study of crime has always been rooted in scientific positivism. Scientific positivism involves the application of the scientific method, where traits and characteristics are operationalized, measured, and analyzed in an effort to detect patterns of covariation. The movement toward biological explanations of crime was most notably spurred by the nineteenth century physician and Italian positivist named Cesare Lombroso.

Often adorned as the father of positivism, Lombroso studied thousands of individuals incarcerated in Italian prisons, documenting many physical and environmental differences he thought potentially related to criminal behavior. Lombroso is often reduced to his thoughts on the 'atavistic man,' – that is, his beliefs that a minority of criminals were biologically less advanced than others and that atavists shared many physical characteristics with primitive humans. Less recognized is that Lombroso also thought that most criminal offending could be explained by environmental and biological factors and that his 'atavists' represented a very small fraction of the offending population. Nonetheless, Lombroso examined thousands of individual criminals and noted several shared physical characteristics such as muscular builds, low foreheads, broad noses, larger jaws, and smaller cranial vaults. He concluded that criminals were often, but not always, biologically different from others and that some were born with a natural inclination toward pleasure-seeking and criminal conduct. These observations and conclusions were chronicled in his famous work, *The Criminal Man* (1911). Lombroso's early studies inspired other scholars to conduct similar research regarding the correlations between physical characteristics and criminality (Hooten, 1939; Jacobs, 1965).

The Italian positivists focused on specific physical characteristics of offenders and attempted to correlate those differences with criminal behavior. Throughout the 1800s and early 1900s, biological explanations of crime were well received and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45086-5

supported as scientific advancements in the study of human nature. However, as society began to rapidly change in both Europe and the United States, political movements began to paint a very different picture of the biological approaches to crime. The rise of totalitarian governments, namely Fascist Italy and Nazi Germany, gave way to some of the most horrifying political movements in modern history. These totalitarian governments, scholars would later point out, sometimes used biological explanations to justify their repressive state actions. The same was true in the United States with the rise of the 'Progressive Movement' and their related acceptance of eugenic social policies. The progressive political movement, often linked to the ascendancy to modern-day liberalism, advocated the forced sterilization of men and women as a method to control the social and financial costs of socially undesirable populations. The eugenic movement went on to inform Nazi efforts to eradicate unwanted groups.

Collectively, the Nazis and the Progressives shared a view that they could socially engineer a better society if government controlled sexual reproduction. To advance their agendas, they used evidence and theories found in the biological sciences to justify state intervention in sexual reproduction. This movement reached its peak during World War II through the early 1950s, but forced sterilizations continued in the United States through the 1970s. Nonetheless, biological explanations of human behavior and human differences quickly fell out of favor as they became politically fused to some of the worst atrocities the world had witnessed.

Even after totalitarian, governments were disbanded and the eugenics movement ended, biological approaches to crime remained taboo. In the United States, there was a radical change in culture in the 1960s with the emergence of civil rights movements. While the civil rights movements brought instrumental and much needed change in society, it also radicalized the field of sociology. Criminology at the time was part of sociology, and sociology had a long history of excluding biology and the study of individual differences. Many of the emerging scholars during this time period were radicals who were highly influenced by civil rights, feminism, and anticapitalism campaigns. The radicalization of sociologists during the 1960s is important because these scholars became the gatekeepers of ideas and they did not hesitate to sanction individual scholars interested in the biological bases of behavior. Thus, liberal ideology focusing on social processes and environmental experiences became the dominant paradigm in criminology, specifically, and in much of the rest of the social sciences. In rapid succession, social process and social structural theories, such as social disorganization theory, differential association theory, and social bond theory, emerged as the sole focus and explanation of crime. Thus, from the 1960s until recently, the social sciences was fundamentally opposed to explanations of individual differences, rejecting biological explanations on ideological rather than scientific grounds. Scholars attempting to revitalize the study of personality, biology, and individual differences were painted as racist, classist, or sexist. Biological theorizing, moreover, was seen not only as undesirable but also as something to be sanctioned, and scholars who conducted research in this area were essentially black listed and socially ostracized.

The study of biological influences on crime would have completely disappeared from criminology had it not been for the scholars who courageously continued to study and highlight the importance of biological influences – sometimes at great personal cost. One individual was E.O. Wilson. E.O. Wilson's (1975) book, *Sociobiology: The New Synthesis*, stirred tremendous controversy. Wilson's book discussed ants and applied basic evolutionary perspectives of ants to human beings. As Wilson discussed individual differences and evolution rather than social processes, his brilliant insights were heavily criticized by scholars, especially those in the social sciences.

Nearly a decade later, Wilson and Herrnstein's (1985) book, *Crime and Human Nature: The Definitive Study of the Causes of Crime*, was released, showcasing individual differences in traits such as aggression and intelligence as strong predictors of a variety of negative social outcomes. Wilson and Herrnstein's (1985) work brought on a firestorm of scathing criticisms from a myriad of social science scholars. The influential book was rejected by the criminological community and is still seen today by radical criminologists as a dark mark in the history of social science literature. The 'nature versus nurture debate raged on, however, and despite the controversy surrounding these works and the study of individual differences, authors such as Wilson and Herrnstein inspired a handful of other brave scholars. Individuals such as Lee Ellis, Anthony Walsh, David Rowe, and Adrian Raine adopted and maintained allegiance to the biological perspective.

Influenced by these multidisciplinary scholars and excited by new lines of research, an ambitious crop of scholars emerged at the turn of the century. These scholars sought to integrate biological discoveries into modern criminological theories. From this group of researchers, the biological approach to crime evolved into a broader research agenda including not only findings from biology, neurology, psychology, and medicine but also the way these individual differences interact with traditional sociological principles surrounding the individual's environment.

The modern biosocial approach emphasizes the connection between biology and environment, asserting that both nature and nurture are important and that both can interact across time. Because scholars study the way that biology influences social outcomes and the socialization process, the term biological was replaced with the term biosocial, integrating both biological explanations and sociological explanations of criminality. This new biosocial approach has grown exponentially in the last decade, producing more research and interested young scholars than ever before. While many criminology programs across the nation have yet to include biosocial criminology in their curriculum, several programs are beginning to add biosocial classes, attracting cohorts of young scholars eager to learn about the discoveries of biosocial criminology. While the biosocial approach is still met with resistance and criticism, it has emerged as a powerful and pervasive presence in modern criminology.

The biosocial paradigm involves a broad range of topics focusing on individual differences and their connection to criminality. This includes a myriad of topics surrounding personality traits, antisocial behavior, aggression, self-control, psychology, brain structure and function, hormones, and

gene x correlations and interactions. In general, the many subjects falling under the umbrella of the biosocial approach can be categorized into four main areas of study: evolutionary perspectives, behavioral genetics, molecular genetics, and brain-based studies.

Evolutionary Perspectives

Why are men more prone to aggression and violence than women? Evolutionary theory asserts that the reason lies in our evolutionary history (Fergusson and Horwood, 2002; Krueger et al., 1994). Darwinian evolution is built on the principles of natural selection and reproductive processes. Natural selection is the process by which certain traits are passed on through time because they are beneficial and aid in adaptation to the environment, while other traits are selected against and filtered out over time. When humans first evolved, they were faced daily with dangerous tasks of hunting predators, securing shelter, and locating a source of water and nourishment. Males were particularly adept at hunting and at protecting the family unit or tribe, while females were more adept at gathering food, and nurturing and protecting children. These tasks required different traits. Males needed high levels of aggression to track down and to kill prey, and they had to be able to ward off competing tribes. Additionally, men needed to secure females for reproductive purposes. Males who were larger and more muscular in stature were, the theory goes, viewed by females as the most desirable and capable mates. As such, natural selection preserved traits most beneficial to each sex, creating pronounced physiological and psychological differences between males and females.

Crime is often concentrated in families. Several family studies indicate that criminal family members, especially parents, are an important correlate of criminality (Farrington et al., 2001; Farrington, 2002; McCord, 2007). Why do we often see cycles of criminality in families, generation after generation? Evolutionary psychology points to assortive mating as a likely culprit. Assortive mating is the process by which individuals select mates that are similar to themselves. Research indicates that individuals particularly choose partners similar in traits such as intelligence, personality, antisocial behavior (Krueger et al., 1998; Rhule-Louie and McMahon, 2007), and even similar political orientation (Alford et al., 2005; Kandler et al., 2012). Essentially, this means that antisocial individuals often gravitate toward one another. Children of two antisocial individuals thus inherit not only their parents' genes but also the antisocial environment produced by the parent. Owing to this insight we can better understand how problem behaviors and criminality become segregated within some families, but not others, and why crime can be transmitted across generations.

Behavioral Genetics

Can criminality be inherited? Behavioral genetics is a branch of genetic studies, which seeks to find answers to this question. Behavioral genetic studies analyze the contributions of genes and environment to a variety of traits such as intelligence, self-control, aggression, and impulsivity. Behavioral genetic studies attempt to quantify the extent to which genetic factors influence a specific trait. This estimate is known as heritability. Nearly, all traits are heritable to some degree, and behavioral genetics examines the degree of heritability in a variety of traits associated with criminality. Behavioral genetic scholars emphasize that genes do not cause people to become criminal but rather that genes can facilitate dispositions to respond to environmental stimuli in criminal ways. There is no specific gene for criminality. However, some genes may lead to traits such as low self-control and low empathy, which, when combined with a dysfunctional environment, may increase the probability of criminal behavior.

This line of research also examines continuity and change of traits over time. Many studies find that traits such as self-control and aggression remain relatively stable across the life course (Beaver and Wright, 2007; Haberstick et al., 2006; Huesmann et al., 1984; Vazsonyi and Huang, 2010). Studies have analyzed individuals in very early childhood up through adulthood finding that antisocial behavior remains stable across time and is therefore identifiable very early in life (Caspi, 2000; Caspi and Moffitt, 1995; Rose et al., 1989). Behavioral genetics research also examines the sources of stability and change in traits. Specifically, behavioral genetics studies examine the amount of variance in a trait such as impulsivity that is attributed to genetics and the amount of variance that is attributed to environmental factors. The two main studies that help answer these questions are adoption studies and twin studies.

Adoption studies compare adopted children to their adoptive and to their biological parents. Hutchings and Mednick (1977) conducted a study of male children who had been adopted early in life. They gathered criminal records of both the adoptive and biological parents and followed the sample of boys into adulthood. The criminal records of the biological parents were statistically predictive of the children's criminal records – more so than were those of the adopted parents. These findings support genetic influences in criminality. However, some scholars point out that adoptive parents may be matched by agencies and be similar to the biological parents. In response to these criticisms, another line of studies emerged. Researchers examined twins that were raised apart from one another in unique environments. A study done at the University of Minnesota examined twins who were separated at birth and reared apart. Researchers found that twins were very similar in terms of personality, antisocial tendencies, and criminal behavior even when coming from very different social environments (Bouchard et al., 1990). These findings indicate that genetic factors play a role in criminality.

Extending beyond the observational nature of adoption studies, twin studies allow researchers to statistically estimate genetic and environmental contributions to specific phenotypes by comparing monozygotic (identical) twins to dizygotic (fraternal) twins. Monozygotic twins share 100% of their genes, while dizygotic twins share, on average, 50% of their genes. If there is a genetic effect, monozygotic twins should be more similar than dizygotic twins. If twin 1 scores high on impulsivity and twin 2 scores high on impulsivity, their outcome is concordant. If one is high and the other is low, the outcome is discordant. Higher concordance rates among monozygotic

twins as compared to dizygotic twins indicate a genetic effect as environmental influences, such as family, are expected to be similar. However, this method does not perfectly tease apart the variation in a trait as some concordance among twins may also be due to other environmental experiences such as similar peer groups.

Another statistical method in behavioral genetics is using the standard ACE model. The ACE model compares monozygotic twins and dizygotic twins but rather than simply calculating concordance rates, this statistical technique breaks down the variation in a trait into three estimates. The 'A' term is equal to the proportion of variation attributed to genetic factors, which is also known as heritability. The environmental contributions are broken down into shared/common environmental factors (C), such as the family, and nonshared/unique environmental factors (E), such as peer groups or work groups. The ACE model compares the correlations between monozygotic and dizygotic twins and decomposes those correlations into genetic, shared environmental, and nonshared environmental contributions, with the sum of the squared estimates adding to 1.00. Many studies that have employed ACE models indicate that genetic effects for traits such as low self-control, aggression, and antisocial behavior are dominated by genetic influences, with estimates typically ranging from 50 to 95% (Rhee and Waldman, 2002). Another trend in longitudinal studies is that while the genetic effects grow stronger across time, the effect of shared/common environmental influences decreases over time. As children age, nearly all of the variation in their behavioral traits is attributed to genetic and nonshared environmental factors. Behavioral genetics research has identified consistent predictors of criminality that are identifiable early in life, that remain stable across the life span, and that are predominantly genetically influenced. This line of research has helped highlight the importance of early identification and treatment of problem behaviors.

Molecular Genetics

Genes make us who we are. Genes are behind virtually all traits, from the color of our eyes, our height, and other physical characteristics to our personality, intelligence, and our behavioral tendencies. We also know that genes interact with our environment and in turn, our environment can have reciprocal effects on our genetic makeup. While behavioral genetics focuses on heritability of traits, molecular genetics examines specific genes, proteins, enzymes, and genetic combinations and how they interact with environmental stimuli. Genes do not directly affect our behavior. Rather, genes interact with other stimuli such as abuse, to indirectly affect a behavioral outcome, such as aggression. The completion of the Human Genome Project has allowed researchers to identify and study the indirect effects of particular genetic material on behavior and social outcomes. A particular gene of interest is the MAOA gene. Caspi et al. (2002) conducted an extensive longitudinal study of the interaction between variants of the MAOA gene and abuse/neglect during childhood on violent and antisocial behavior in adulthood. Specifically, the authors measured whether the subjects had been arrested for a violent crime in adulthood. In general, low-activity variants of the MAOA gene are a risk factor for violent behavior, while the high-activity variant is generally a protective factor. Results indicated that neither the environmental risk factor of abuse/neglect nor the genetic risk factor of the low-activity MAOA gene was predictive of arrests for violent crime. However, those individuals with the combination of the low-activity MAOA gene and abuse/neglect in childhood were nearly 10 times more likely to have been arrested for a violent crime than those who had neither the genetic nor the environmental risk factor. Additionally, while subjects with both genetic and environmental risk factors comprised just 12% of the sample, they were responsible for 44% of the violent crime arrests (Caspi et al., 2002). Other studies have also confirmed interactions between maltreatment and the MAOA gene on antisocial behavior (Haberstick et al., 2005; Kim-Cohen et al., 2006). Certain gene sequences and variants have also been associated with alcohol abuse and related behaviors (Heath et al., 1997; Wang et al., 2008).

Other important discoveries involve the effects of differential levels of hormones such as testosterone and estrogen. Research indicates that men with elevated levels of testosterone and other androgens are more prone to risk-taking behavior and aggression, both of which are linked to criminality (Ellis, 2005). Neurotransmitters, chemicals that pass electric signals between neurons, also play an important role in regulating emotions and decision making. In particular, low levels of serotonin, an important chemical in both cognitive and emotional processing, is associated with aggression, impulsivity, and criminal behavior (Blumensohn et al., 1995; Coccaro et al., 1997; Ellis, 2005). The identification of hormones, neurotransmitters, and specific gene variants and their interactions with the environment has been an important step in further understanding criminality (Raine, 1997).

Brain Studies

The brain is a remarkably complex, vital, and fragile component of human life. The brain controls everything from bodily functions to cognitions to emotions. Scholars from medicine, neurology, biology, and other hard sciences have always recognized the importance of the brain in shaping human behavior. It is just recently that criminological scholars are beginning to recognize the role of the brain in explanations of criminality. Damage to the brain can result in a myriad of problems involving cognition, perception, sensation, memory, and impulse and emotional regulation. The limbic system sits atop of the brain stem and is within the cerebrum. Damage to particular areas of the brain has been linked to criminality. Problems with the frontal lobe are consistently associated with criminal behavior. The frontal lobe is located directly behind the forehead and contains the prefrontal cortex, an area of the brain responsible for executive functioning. Executive functioning includes tasks such as planning, decision making, delaying gratification, impulse control, and anticipation of consequences. Chronic offenders typically display executive dysfunctions. Another area of the brain, the limbic system, communicates with other parts of the brain and helps balance emotional and rational impulses. In particular, a structure

called the amygdala is responsible for emotional regulation. Problems with the amygdala and limbic system often manifest as individuals with high levels of impulsivity and aggression (Ogilvie et al., 2011).

Research indicates that damages and dysfunction in the frontal lobe are linked to criminality. Many of these functional and structural issues are highly heritable (Rafter, 2008). Just as genes and environment interact, the environment may also have important effects on the brain. Longitudinal studies of Romanian orphans, Chugani et al. (2001) and Eluvathingal et al. (2006), found that those orphans who had experienced severe emotional deprivation had brain abnormalities and were cognitively underdeveloped relative to the comparison group. Other studies have highlighted the effects that alcohol and drug abuse have on the brain, noting that prolonged abuse can physically alter an individual's brain structure (Volkow and Ting-Kai, 2004). Differences in individual brain structure and function have also been observed in individuals with conduct disorder, schizophrenia, and tendencies toward risk-taking behaviors (Decety et al., 2008; Gogtay et al., 2004). Clearly, the brain structure and function plays a crucial role in criminality.

Moving Forward

The biosocial approach to crime has had a unique and critical impact on criminology. Biosocial approaches have revitalized and highlighted the importance of individual differences, an insight that was ignored for several decades. Differences in personality, intelligence, self-control, aggression, executive functioning, and a host of other biological and physiological factors explain differences in criminality. These individual differences emerge early in life and can be identified in early childhood. Furthermore, traits such as personality, aggression, and self-control remain relatively stable across childhood, through adolescence, and into adulthood. Focusing prevention and rehabilitation efforts on only adolescents and young adults is inefficient. These findings implicate the need for early detection of problem behaviors and early intervention strategies before serious social outcomes manifest.

While bringing the focus of criminology back to the individual, biosocial approaches do not refute the importance of the individual's environment. Genes and biology interact with environmental stimuli. Specifically, findings indicate that environmental factors such as parenting styles, attachment, and abuse/neglect can affect the expression of genes and the manifestation of behavioral outcomes. The more we learn about how biology, especially our genes and brain chemistry, is related to criminal behavior, the more we come to understand the importance of environmental influences. There is no need for the nature versus nurture debate to continue. Rather, we may look at the connection between biology and criminality as nature via nurture. Inadequate parents, poor socialization, deviant peer groups, and other negative environmental stimuli play important roles in individual development, but criminological theories that exclude the effects of biological factors are incomplete. As stated by former American Society of Criminology and former American Criminal Justice Society president, Dr Francis T. Cullen, at the 2010 American Society of Criminology Sutherland Address:

> As we move forward, however, we can no longer pretend that biology is not intimately implicated in human behavior and thus in criminal behavior. Knowledge about genes and how brains operate is exploding, and it is influencing other social scientific fields—including even sociology… In the end, we truncate reality if we do not study what we all now know: Babies emerge from the womb with individual differences, which then influence the lives that they will help to create.

There is an overwhelming amount of evidence across disciplines that point to the direct and indirect influences biology has on behavior. Genes and neurological deficits matter. Study after study has found that genes have a profound impact on human development and behavior and that genetic influences account for the majority of variation in criminality, followed by nonshared environmental influences such as delinquent peer groups. Scientific advancements and discoveries have allowed scholars to conduct more sophisticated analyses of heritability estimates, effects of brain structure and function, the presence of certain gene and enzyme combinations, and the gene × environment interactions related to criminality. While limitations remain, the biosocial approach has helped advance the methodological standards of empirical research in criminology. Despite the ideological obstacles, skepticism, and controversies surrounding biosocial criminology, the growing interest and productivity of this line of research is unparalleled in the field of criminology. Regardless of those who oppose the application of science in the study of criminality, the biosocial approach is the future of criminology. Biosocial criminology has and will continue working to integrate theories from a variety of fields using empirically sound research to enrich our understanding of criminality.

Abstract

This article surveys the rise of biotechnology since the closing decades of the twentieth century, examining both scientific developments and social and institutional change. As an area of science and technology with the explicit goal of intervening in the machinery of life, biotechnology often disrupts traditional ways of distinguishing 'nature' from 'culture,' calling into question settled social arrangements. As a result, biotechnology poses difficult challenges of governance. This article examines the rise of biotechnology and considers its technological and epistemic dimensions, then turns to its institutional aspects and problematic position in contemporary politics. The role of risk management and bioethics in legitimation are also discussed.

In the closing decades of the twentieth century, biotechnology emerged as a site of rapid change in science and technology and as an arena of social and institutional transformation. The development of new techniques for studying, manipulating, and redesigning living things produced important applications in medicine and agriculture, and generated massive investment. In the world of research, biotechnology was often at the forefront of change in scientific institutions and practices. More broadly, biotechnology – widely perceived as having 'revolutionary' implications – inspired both intense enthusiasm and determined opposition. As an area of science and technology with the explicit goal of intervening in the machinery of life, biotechnology often disrupts traditional ways of distinguishing 'nature' from 'culture,' calling into question settled social arrangements. The potential for change associated with emerging biotechnologies thus has presented societies with normative choices about the kinds of futures they seek to create, sparking controversies about new hopes, risks, subjectivities, and ethical dilemmas. As a result, biotechnology poses difficult challenges of governance. This article surveys the rise of biotechnology, examining its technological and epistemic dimensions, its institutional aspects, and problematic position in contemporary politics.

The Term 'Biotechnology'

Defining biotechnology poses challenges, for the word is less a tightly defined, technical term than a loose umbrella category, or even a slogan, that conveys – sometimes simultaneously – visions of unbounded progress and unregulated tampering with nature. Many authors have tried to capture biotechnology within their own well-crafted definitions, but these attempts cannot neatly contain this expanding network of activities and increasingly dense connections to diverse social worlds. Although the word has a long history (Bud, 1993), in most contemporary contexts biotechnology refers to a novel and growing collection of techniques, grounded in molecular and cell biology, for analyzing and manipulating the molecular building blocks of life. The term also designates products, such as pharmaceuticals or genetically modified (GM) foods, created using these techniques. At times, it refers not to products or techniques but to an economic sector or area of research. Biotechnology acquired these intertwined meanings toward the end of the 1970s, coming into widespread use in the early 1980s, as molecular biology was increasingly understood not only as a 'science' for learning about nature but also as a 'technology' for altering it.

The Biotechnology 'Revolution'

One of the ironies of the rise of biotechnology is that a sense of revolutionary potential energizes both the enthusiasm and the opposition it engenders. Supporters and critics alike often fit biotechnology into a narrative of radical discontinuity (e.g., Carlson, 2010; Conway, 1997; Kevles and Hood, 1992; Rifkin, 1983; Kass, 2002). Biotechnology advocates claim that it will completely transform medicine, spawn entirely new industries, and supply adequate food to the growing world population. Critics – who warn of unanticipated consequences and the hazards of altering human identity – also cast the new biology as a revolutionary force, arguing that genetic engineering is ushering in a risky new stage in evolution, as nature itself comes under technological control.

Alongside the notion of revolution, the discourse on biotechnology also features an opposing frame that stresses continuity with the biological and historical past. Thus, supporters of biotechnology sometimes downplay its novelty, defining it inclusively (e.g., as the harnessing of biological agents to provide goods and services) and portraying it as merely the latest twist on age-old methods of plant breeding, animal husbandry, and brewing. Such moves help to make the exotic familiar, to suggest that ancient precedents justify apparently novel practices, and to undermine the notion of an untouched 'natural' order that must be protected from human intervention. Critics of biotechnology, for their part, often contend that predictions of unprecedented progress overstate the benefits, suggesting that biotechnology will perpetuate, rather than eliminate, long-standing inequalities in agricultural and health care systems.

As these observations suggest, narratives of continuity and discontinuity provide opposing frames that participants in debates about biotechnology can selectively deploy to mobilize

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85046-1

support for their views. But for social scientists, the relevant question is whether the concept of a biotechnology revolution has analytic utility. Although some might be tempted to dismiss this notion as overheated rhetoric or media 'hype,' revolutionary rhetoric and mass media coverage play a constitutive role in shaping biotechnology (Fortun, 2008; Hilgartner, 2012). Like information technology and computers, biotechnology seems perpetually to stand at the threshold of the next qualitative transformation (*see* Science and Technology, Social Study of: Computers and Information Technology). Emerging technologies exist not merely in material form, but also as expected or imagined futures built in part of hopes, fears, and promises that drive speculation and have effects in the present (Brown et al., 2000; Fortun, 2008; Nelson et al., 2008; Rabinow and Dan-Cohen, 2005). Biologists who pause to marvel at the pace of progress, like ordinary citizens who reflect on the stream of announcements from the research front, experience biotechnology as an area of ongoing change where old boundaries are continually broken and the unprecedented rapidly becomes the mundane.

A New Technological and Epistemic Space

Whether framed as revolutionary change or incremental evolution, there is no doubt that biotechnology has grown increasingly prominent since the 1970s, inspiring the growth of an increasingly global, 'big biology' (Davies et al., 2013). Biotechnology emerged from a complex constellation of phenomena, among them the development of increasingly powerful means for representing and manipulating the molecular building blocks of life. At the level of infrastructure, the routinization of practices for culturing biological tissues transformed cells into tools for investigating their own operation (Landecker, 2007). Beginning in the early 1970s, the development of a cascade of novel techniques – especially recombinant DNA (rDNA) technology, monoclonal antibodies, *in vitro* fertilization, the polymerase chain reaction (PCR), and high-throughput DNA sequencing – dramatically extended human control over living organisms. Although the arrival of each of these techniques was widely heralded as 'revolutionary,' the growing power of biotechnology cannot be attributed to any single tool, but stems from the ability to combine and recombine such tools, creating new assemblages capable of building and taking apart molecules, rearranging the genetic code of organisms, and reading, analyzing, and writing the 'language' of DNA with an increasingly integrated set of laboratory techniques and computational tools. No less significantly, such techniques have consolidated and accelerated epistemic change in the life sciences, increasing the centrality of metaphors from information theory and cybernetics (e.g., code, control, and text) for understanding living things (Kay, 2000; Keller, 1995, 2002). More precisely, these tools provide practical means that, quite literally, lend substance to these metaphors, giving them material form and making them into epistemic things embedded in experimental systems (Rheinberger, 1997) and sociotechnical networks (*see* Experiment, in Science and Technology Studies).

The field of molecular biology expanded rapidly after World War II (de Chadarevian, 2002), and by 1970, scientists knew how genes specify protein structures and had found enzymes that cut, join, and extend DNA molecules. This set the stage for rDNA technology – the emergence of which is often taken as the starting point for modern biotechnology. rDNA techniques enabled scientists for the first time to insert or delete genes from the genetic code of living things, for example, by removing a piece of DNA from one organism and splicing it into the DNA of a distantly related species. The development of these methods generated great excitement and provoked controversy (discussed below) about the wisdom and safety of genetic engineering. Beyond opening up a wide range of new research strategies, this technology allowed scientists to design genetically modified organisms (GMOs) to produce commercial products. In the late 1970s, researchers began using genetically engineered bacteria as microscopic manufacturing plants for making valuable proteins, such as human insulin and human growth hormone.

In the last two decades of the twentieth century, the power of the biotechnology tool kit continued to increase. The development of monoclonal antibodies, which permitted scientists to construct extremely accurate assays for detecting specific proteins, yielded applications in research and medical diagnostics (Cambrosio and Keating, 1995). New methods for transferring genes into developing embryos allowed scientists to alter the genetic code of animals, thus extending genetic engineering from microorganisms to higher forms of life. Parallel techniques enabled scientists to produce transgenic plants (Nelson, 2012), and research aimed at improving the genomes of agriculturally important crops became a major focus of the plant sciences. Molecular biology and biotechnology also played an increasingly central role in the development of pharmaceuticals, including vaccines, antibiotics, and drugs used to combat heart disease, cancer, and AIDS.

Tools and practices for representing and analyzing DNA molecules were also rapidly developed (Fujimura, 1996). Methods for mapping the location of genes grew increasingly powerful; PCR became important in research, diagnostics, and forensics (Rabinow, 1996b); and DNA sequencing – a technique for representing the nucleotide sequences of DNA molecules as written inscriptions (strings of the letters A, C, G, and T) – rapidly developed. In the 1990s, the Human Genome Project, along with other concerted mapping and sequencing efforts, produced an exponentially increasing volume of biomolecular data on a variety of organisms of medical and agricultural importance (Cook-Deegan, 1994; Gaudillière and Rheinberger, 2004). New 'factory-style' laboratories dedicated to sequencing also emerged during the human genome project, and in the years since the completion of a 'first draft' of the human sequence was announced in 2001, a new generation of sequencing machines spurred a continuing exponential increase in the production of sequence data (Hutchison, 2007). These data – along with increasingly automated means of producing, standardizing, ordering, and analyzing them – constitute the core resource of genomics and bioinformatics, fields that have further united information science and biology. In effect, by opening up new computational approaches to biology, genome data have created a new technological and epistemic 'space,' allowing researchers to perform

'experiments' *in silico* or in a domain linking computational work to the 'wet lab.'

Developments in cellular biology also expanded the reach of biotechnology. In 1997, a team of Scottish researchers announced that they had cloned a sheep, who they named 'Dolly,' using a technique called somatic cell nuclear transfer (SCNT). Put simply, Dolly was a 'copy' of an adult ewe created by transferring the nucleus of one of the adult's cells into an enucleated sheep egg and implanting it in another ewe using *in vitro* fertilization. This feat – the first successful cloning of a mammal – suggested that cloning of human beings could also be achieved, sparking controversy around the world about the ethics of human cloning. At about the same time, the discovery of embryonic stem cells (ESCs) suggested a novel strategy for attacking a variety of human diseases. Because ESCs can differentiate to form a wide range of tissue types, they could potentially be used to create replacement tissues to restore function to damaged or diseased organs or systems. Stem cell research inspired great hope and significant investment, but like SCNT, human ESC research also provoked controversy. In many countries, the destruction of human embryos to 'harvest' stem cells generated determined opposition, although the cross-national differences were significant (Prainsack, 2006).

In recent years, biologists and biotechnologists have (often quite self-consciously) advanced new 'paradigms' for research and technology development. One notable development is the rise of 'systems biology,' which seeks to holistically examine the interactions of systems of biological components, tracking their operation quantitatively using computational and mathematical techniques (Calvert, 2013). Another is 'synthetic biology' – an effort that seeks to apply engineering principles to make biotechnology into a true engineering discipline (Campos, 2012; Carlson, 2010; Pottage, 2006). Rather than modifying existing living organisms as biotechnologists presently do, synthetic biologists imagine creating entirely new biology-based devices and systems. Several strategies for achieving this have been proposed, including a scheme based on creating standardized biological 'parts' (or 'biobricks') analogous to electronic components; the idea of using a 'minimal genome' as a 'chassis' for constructing organisms; and the possibility of engineering novel nucleic acid chemistries of human design. Synthetic biology has generated much excitement, but the field is still in its infancy and how and whether it will mature remains an open question.

Institutional Dimensions

Large infusions of capital, promotional state policies, and novel institutional arrangements played a significant role in spurring these developments (Thackray, 1998). By the end of the 1970s, government, industry, and academic elites in both Europe and the United States saw investment in 'high technology' – especially computers and biotechnology – as the long-term prescription for economic growth. On both sides of the Atlantic, policymakers sought to spur innovation and speed the translation of basic science into marketable products. The result: a significant shift in the political economy of research that eased the commodification of knowledge (*see* Patenting in the Biological Sciences). Governments encouraged universities and corporations to form new kinds of academic–industry alliances, and the scope of intellectual property protection grew considerably broader, expanding to encompass, for example, genetically engineered organisms (Boyle, 1996; Jasanoff, 1995; Hilgartner, 2009). These developments – along with increasing globalization of not only the economy but also research and development – have contributed to the emergence of new forms of economic activity and what some have termed 'biocapital' (Sunder Rajan, 2006; Helmreich, 2009).

In the United States during the 1980s, significant numbers of academic biologists became entrepreneurs for the first time, seeking to launch new biotechnology companies that many imagined at the time might soon grow into enormous firms. The most dramatic institutional innovation was the start-up company founded by venture capitalists and university professors – many of who kept their academic posts (Kenney, 1986). Increasingly, biotechnology research took place in spaces that were not neatly lodged in either an academic or a corporate milieu, but in complex hybrids of university and industry, public and private, and basic and applied research (*see* Universities and Science and Technology: United States). Some observers warned that these hybrids would threaten the independence of academic biologists, weakening the research system and compromising their ability to offer a credible, critical voice in public decision-making. Debate continues about whether these developments represent a threat to the moral and intellectual integrity of university science (Mirowski, 2011; Shapin, 2008), but ultimately these institutional innovations proved irresistible, given competitive pressures and the scientific and economic opportunities.

Owing to international variation in research systems, the commercialization of biotechnology followed distinct paths in different nations. In Europe and Japan, the large multinational corporations (MNCs) that controlled production of pharmaceuticals, chemicals, and agricultural inputs tended to build biotechnology directly into their in-house research operations. But in the United States, with its unique pattern of venture capital financing, a separate 'biotechnology industry' composed of freestanding firms took shape (Kenney, 1998). The first major wave of biotechnology firms appeared between 1979 and 1981, and in the following three decades, entrepreneurs founded successive waves of firms, whipping up investor enthusiasm around a series of 'revolutions,' including monoclonal antibodies, gene therapy, genomics, stem cell research, and synthetic biology.

Even in the United States, however, MNCs – which poured huge sums into genetic engineering, rational drug design, and genomics – became the dominant players in efforts to exploit the new biology commercially. Indeed, given the structural connections between the biotechnology firms and the MNCs, the image of a separate biotechnology industry is somewhat misleading: Biotechnology start-ups often derive the bulk of their revenue from contracts with giant companies; MNCs often acquire successful firms; and many

biotechnology firms are best understood as research shops that hope to sell intellectual property to large corporations. But if efforts to exploit the new biology are increasingly the province of both large and small firms, the culture of the biotechnology start-ups that emerged in the United States captured the imagination of science policymakers elsewhere, some of whom have sought ways to stimulate parallel developments. More broadly, policy analysts are promoting the goal of stimulating the growth of the 'bioeconomy' – a term defined inclusively to reach beyond health and agriculture to include the production of fuels, the recycling of materials, and the manufacture of plastics, paper, and industrial chemicals (OECD, 2009).

The Politics of Biotechnology

Since the early 1970s, biotechnology has posed difficult problems of governance, confronting societies with a stream of potentially controversial issues. The expanding applications of biotechnology – which moved quickly from being mainly a research tool into being an important part of medicine and agriculture – significantly increased the numbers of actors with normative ideas about its proper use. The development of DNA forensics (Lynch et al., 2008; Hindmarch and Prainsack, 2010), the advent of genetic tests that yielded predictive information about the onset of future disease (Parthasarathy, 2007; Hedgecoe, 2004), and the rise of 'biobanks' of samples of people's DNA (Gottweis and Petersen, 2008) all raised questions of governance. Biotechnology also got entangled in the politics of race, as scientific research projects intended to study human diversity raised persistently troubling questions about how to represent human similarity and difference (Reardon, 2005; Koenig et al., 2008). In the aftermath of the terrorist attacks of 11 September 2001 and the anthrax attacks only days later, the military potential of biotechnology grew into a prominent security concern (Balmer, 2012; Vogel, 2012). Indeed, as biotechnology grew increasingly entangled in a variety of social institutions, as it was integrated into more and more aspects of everyday life, societies throughout the world confronted a stream of normative questions about how to fit biotechnology into their ways of living in the world.

Finding legitimate settlements to these controversies sometimes proved difficult. Because biotechnology often seems to undermine basic categories of social order, such as the 'natural' or the 'human,' it tends to pose problems that do not fit neatly into the cosmologies and routines that guide public action. Democratic societies, thus face the challenge of building new discursive regimes, regulatory mechanisms, and forums for public discussion that can narrow disputes and achieve legitimacy. In this respect, the institutionalization of risk management and bioethics have been particularly important. Although, the precise techniques for engineering consent have varied across nations (Gottweis, 1998; Jasanoff, 2005), states have consistently responded to opposition in ways that allowed the development of biotechnologies to proceed. Despite a cascade of visible controversies, states have generally managed to convert volatile mixtures of concerns into more stable forms. In culturally specific ways, unstable blends of technical uncertainties, science fiction scenarios, critiques of corporate power, and misgivings about hubris and slippery slopes, have largely been discursively distilled into categories amenable to bureaucratic management and expert decision-making (Jasanoff, 2012).

Risk Management

The process of 'thinning' multidimensional controversies into manageable technical problems susceptible to regulatory solutions is well illustrated by what has come to be known as the rDNA debate (*see* Risk, Sociology and Politics of). During the 1960s and early 1970s, scientists and other observers often construed the arrival of genetic engineering – viewed, once again, through the frame of radical discontinuity – as a portentous development that raised many troubling choices for society. As researchers became convinced that molecular techniques would soon make it possible to modify the genomes of living organisms, a number of prominent scientists warned that developments in biology could be dangerously misapplied, and they called for broad public discussion of such possibilities as the genetic engineering of humans. However, soon after researchers began splicing genes into bacteria and viruses, the focus of discussion shifted from broad concerns about the long-term implications of genetic engineering to much narrower and immediate questions about the laboratory hazards of rDNA research (Wright, 1994). In particular, scientists familiar with the early gene splicing experiments worried about accidentally creating dangerous microorganisms, resulting in catastrophic epidemics or disrupting ecosystems. The problem of providing credible scientific arguments that rDNA research could be safely conducted posed significant challenges, given limited evidence and technical debate about the magnitude of the hazards, and in 1974, 10 prominent biologists published a call for a partial moratorium on certain rDNA experiments.

The debate about the 'moratorium' and the physical hazards of rDNA research threw the future of genetic engineering into doubt, but it also allowed broader ethical and political questions to slip into the background (Gottweis, 1998; Wright, 1994). Moreover, scientific experts soon developed a discursive framework that provided a technical strategy for controlling the laboratory risks. This strategy, which took shape at a famous international meeting in Asilomar, California, relied on a system of classification (experiments would be grouped according to their expected level of hazard) and a gradient of controls (e.g., physical barriers, such as negative air pressure, and biological controls, such as 'disarmed' bacterial strains unable to survive outside the laboratory). On both sides of the Atlantic, the strategy of requiring increasingly stringent containment for increasingly risky experiments formed the basis for guidelines or regulatory controls, designed by expert committees that allowed research to proceed.

Containing the microbes within the laboratory became a means of containing fears and allowing genetic engineers to pursue the unbounded possibilities they believed to lie before them. As the 1970s progressed, these controls were

progressively relaxed as a growing number of scientists concluded that the danger of devastating epidemics was remote. Ultimately, the resolution of the controversy inspired a second-order debate about whether scientists, policymakers, and publics had responded appropriately or excessively to the risks of novel organisms. In contemporary debates over biotechnology, the rDNA debate has acquired an almost mythic status (Hurlbut, 2014): at times, it serves as a cautionary tale about the dangers of irrational fear of technology; more often, it provides a commendable example of scientists taking responsibility for the social implications of their work.

In the 1980s and 1990s, new regulatory challenges emerged as agricultural biotechnologists sought to move GMOs from the laboratory to the field – first on an experimental basis and later, in full-scale production (*see* Agricultural Science and Technology). In this context, risk management shifted from containment to deliberate release into the environment, a move that engaged new sources of expertise, such as ecologists, in risk assessment. Nevertheless, fears grew that agricultural biotechnology might accidentally produce new superweeds, alter ecosystems, and expose unsuspecting consumers to the risks of allergic reactions. By the late 1990s, the efforts of US companies, notably Monsanto, to introduce GM crops into Europe were encountering intense opposition from activists warning about the dangers of 'Frankenfoods' and calling for their ban. Framing their arguments in terms of the consumer's right to know, opponents of agricultural biotechnology also demanded that all GM foods be explicitly labeled as such. Soon, the technology was embroiled in a global debate turning not only on issues of safety, narrowly construed, but also on questions of corporate power in agriculture and the danger that reliance on GM seeds would trap the poor farmers of the developing world into dependency. Supporters of agricultural biotechnology contended that GM crops are a green and pro-poor technology, reducing risks from conventional pesticides and conveying useful traits such as drought resistance or nutritional enhancements.

The reaction to GM foods in different countries over the last two decades is too diverse for easy generalization. Extensive controversy broke out in Europe and India, and GM-free movements mobilized in Brazil, South Africa, and elsewhere (Stone, 2010). Jasanoff (2005) provides an instructive comparison of Europe (especially Germany and the United Kingdom) with the United States, where agricultural biotechnology provoked relatively less public reaction. The US Food and Drug Administration was able to 'naturalize' GM foods using a regulatory strategy that defined them as 'substantially equivalent' to non-GM foods, a move that not only allowed GM products to be brought to market but also forestalled labeling. In the United Kingdom, however, the issue could not be contained within the domain of regulatory deliberation. Environmental and consumer groups actively opposed the introduction of GM crops and foods, leading major supermarket chains to withdraw GM products (Jasanoff, 2005), and spurring the government to undertake an inquiry into the public acceptability of GM, including an unprecedented 2-year public participation exercise known as 'GM Nation' in 2001–02 (Horlick-Jones et al., 2007). Opposition movements also took hold on the European continent, and in 1999, five European Union (EU) member states decided to block the introduction of GM products until a system for identifying and labeling them was put into place. In contrast to the United States, the EU decided that rather than treating GM foods and crops (absent evidence to the contrary) as equivalent to their 'natural' counterparts, it would treat them as a class of biological entities requiring regulatory action. Within a few years, the EU had put in place a regulatory framework for labeling GM products and making them 'traceable' as they move through the food system (Lezaun, 2006). The market for GM foods and the percentage of land used for GM crops remain much smaller in Europe than in the United States (Stone, 2010).

Observers have often attributed the contrasting reception of GM foods in Europe and the United States to public ignorance or simple material interests, but careful analysis suggests that the deeper reasons stem from variations in collective modes of public knowledge making and public reasoning – what Jasanoff (2005) calls 'civic epistemologies.' The ongoing debate over GM foods and crops thus suggests that the ability of risk management techniques to depoliticize conflicts over biotechnology is far from universal, depending deeply on specific cultural and institutional contexts, especially at the level of the nation.

Bioethics

The policy narratives and practices of risk management offered one means for translating the unruly politics of biotechnology into governable forms; bioethics offered another – especially, regarding human biotechnology and molecular medicine. The potential of the new biology to destabilize, redefine, or deliberately alter the identities of individuals, groups, or 'human nature' often generated apprehension or resistance, even as it also inspired excitement and opened possibilities for constructing new subjectivities (Rabinow, 1996a; Rose, 2007; *see* Human Sciences, History of; Biomedical Sciences, History and Sociology of). Encounters with genetic medicine often cast people into the problematic role of 'moral pioneers' (Rapp, 2000). Some observers worried that predictive genetic testing would threaten privacy and deprive people of uncertainty about fate; others feared that genetics would reinforce racial prejudices or produce new stigmatized groups; still others objected to the desacralization and commodification of human life. Since the late 1990s, the creation of large collections of human DNA, so-called 'biobanks,' inspired concerns about privacy, control, and governance (e.g., Corrigan and Tutton, 2009). Such worries that did not neatly fit into the technical and economistic discourse of risk management were typically addressed through the interpretive frameworks and institutions of bioethics.

During the 1970s and 1980s, bioethics emerged as an institutionalized area of inquiry and technique for decision-making. The bioethics phenomenon, like the growth of risk management, was by no means confined to biotechnology. In medicine, health care, and clinical research, bioethics – performed in such diverse sites as academic literature, national commissions, hospital ethics committees, and,

most recently, biotechnology corporations – has grown into a prominent feature of public life (DeVries and Subedi, 1998; Kleinman et al., 1999; Rothman, 1991). The rise of biotechnology contributed to the rise of bioethics, fueling its growth with a cascade of controversies about genetic testing, gene therapy, and reproductive technology – matters that increasingly came to be seen as part of the professional jurisdiction of a new cadre of bioethics experts (*see* Science and Technology Studies: Experts and Expertise). Indeed, by the late 1980s, when the Human Genome Project was proposed, the notion that bioethical analysis could play a major role in addressing the societal dimensions of the new biology was sufficiently widespread that national governments flocked to build 'ethics' into their programs of genomics research (Cook-Deegan, 1994).

The peculiar relationship between the domains of bioethics and biotechnology is nicely illustrated by the politics of governmental programs on the ethical, legal, and social implications (ELSI) of genomics. (In Europe, these programs tended to avoid the arguably deterministic word 'implications' in favor of the more open term 'aspects,' and hence were known as ELSA programs.) A broad consensus supporting ELSI/ELSA programs often coexisted with deep disagreement about what these programs should aim to accomplish. The US ELSI program, for example, was celebrated as an important innovation in science policy and presented as proof that social concerns would not be neglected, yet the program was also beset by criticism from many directions. It was accused of being both hypercritical and unduly promotional of genetic technology; of taking an overly academic and long-term view and of narrowly focusing on the immediate; of being too small to address the pace of change and of being a waste of valuable research funds. But such debates about the shape of these programs missed the more pervasive, if subtle, ways that bioethics functions as a quasiregulatory institution in contemporary states. Bioethics provided an idiom and institutional space for defining controversies about human genetics and genomics as ethical issues, better addressed through moral reflection than mobilization. Thus bioethics commissions often served to narrow debate, focusing attention on 'thin' questions of means rather than 'thicker' debate about ends (Evans, 2002).

To be sure, the ability of bioethics to narrow and contain public debate was incomplete, as the controversy about ESCs in the United States nicely illustrates. In this case, debate over ESC research, tightly connected to religious beliefs about the sanctity of life and the divisive national controversy over abortion, ended up being fought in the arena of electoral politics, and the ongoing debate featured attacks on national bioethics commissions for having 'politicized bioethics.' But despite its limitations, bioethics offered a tool for shoring up the legitimacy of political institutions, suggesting that states could find rational and secular means for drawing moral boundaries to replace the apparently natural ones that the biotechnology revolution erased. In this way, bioethics – like other forms of expert advice (Jasanoff, 1990; Hilgartner, 2000) – has become an important means not merely for making decisions but also for reordering societies challenged by rapid technological and social change.

Abstract

Bipolar (manic-depressive) disorder is a severe syndrome involving episodic shifts of mood into mania or depression, with variations in severity, frequency, clinical presentation, and complexity of episodes. Associated risks are high rates of psychosis, anxiety syndromes, and substance abuse. Mortality is increased due to suicide, accidents, and medical complications of substance abuse, as well as stress-sensitive medical disorders. Lifetime prevalence for relatively severe cases is probably more than 2% of the general population, affecting men and women similarly; half of cases begin before age 20. There is a strong familial predisposition but no identified genetics or etiology. Mania sometimes arises in association with neuromedical disorders or reactions to drugs. The long-term course is quite predictable in individuals from early morbidity patterns, but unpredictable across patients. Treatment of mania involves antipsychotics, anticonvulsants, or sedative medicines for mania. Treatment of bipolar depression remains unsatisfactory and the place of antidepressants in such treatments remains controversial. Long-term maintenance treatment with lithium salts or certain anticonvulsants seeks to avoid recurrences, with only partial control, especially of depression. Psychosocial and rehabilitative interventions also are useful components of comprehensive care.

Introduction and Historical Background

Bipolar disorder, a form of manic-depressive illness, is a typically episodic, often severe, and sometimes disabling psychiatric illness characterized by marked changes in mood, thinking, and behavior (Goodwin and Jamison, 2007). Bipolar disorder is a major public health problem, though sometimes underrecognized, and commonly diagnosed as major depressive or other disorders before manic episodes occur; hypomania sometimes is not perceived by patients or recognized by physicians as abnormal mood elevation. Characteristically, symptomatic changes in the disorder present in extremes of mania and depression, or with simultaneous excited and depressive ('mixed') features.

Clinical descriptions of mania and melancholia date at least to Hippocratic physicians (*c*.400 BCE), although early cases probably included neuromedical disorders with associated excitement or withdrawal. Aretæus of Cappadocia (*c*.CE 150) is credited with early descriptions of associations of mania and melancholia in the same person at different times (Baldessarini et al., 2014a). Elaborations of such associations continued during the second millennium, including description of a *manic-melancholic syndrome* by Piquer-Arrufat in the 1700s. In the 1800s, Baillarger and Falret added descriptions of *double or circular insanity*, and Kahlbaum and Hecker described *cyclothymia* (Baldessarini et al., 2014a). At the end of the nineteenth century, Kraepelin conceived a more comprehensive and influential description of *manic-depressive insanity* to include patients with recurrent melancholic episodes and others with manias as well as depressions, along with similar, milder conditions (Trede et al., 2005).

Contemporary distinctions of bipolar (manic and depressive) and unipolar (depressive) forms of recurrent major mood disorders evolved in the writings of Kleist and Leonhard from the 1950s, and later, Angst, Perris and Winokur (Baldessarini et al., 2014a). In the 1970s, bipolar disorder was subdivided into types I (with mania) and II (with only hypomania), both with recurrent depression (APA, 2013). In the 1980s and 1990s, an even broader 'bipolar spectrum' disorder that included recurrent depression with mild hypomania (Goodwin and Jamison, 2007), leading to total lifetime prevalence-estimates of bipolarlike disorders that are similar to those of unipolar major depressive disorders (Angst et al., 2010).

Mania

Episodes of mania present with an increased rate of thinking and speaking, increased physical and sexual energy, decreased need for sleep, changes in appetite, and possible aggressive behavior. Thinking is typically rapid, pressured, overproductive and semilogical, often with a grandiose flavor. As a result, attention and concentration are impaired. Manic persons are often distractible, with continuous shifting of loosely connected topics that can be hard to follow. Attempts to interrupt or restrain pressured behavior often provoke irritable or angry responses. Mania can be associated with paranoid or grandiose delusions. Overactivity is incessant but typically disorganized and unproductive, often without clear or well sustained aims. Abnormal behavior appears to derive from grossly excessive self-confidence, and includes lack of social inhibition, intrusiveness, impulsivity, recklessness, irritability and sometimes aggressiveness. Risk-taking is common, and may include unrealistic plans or implausible business schemes, impulsive overspending or gambling, disinhibited or increased sexual activity, or reckless driving. Impulsivity and impaired judgment can lead to accidents and injuries, especially when complicated by intoxication.

Bipolar Disorders with Hypomania

Fully expressed mania usually involves disruptive or dangerous behavior, usually requiring emergency treatment. *Hypomania* is a milder form of sustained, unnatural mood elevation that may not disrupt occupational and interpersonal relationships, and may require intervention or treatment, but rarely on an emergency basis. In hypomania as well as in mania, judgment and critical self-awareness often are impaired. Hypomania is characteristic of type II bipolar disorder, which presents clinically mainly as recurring episodes of major depression. This syndrome is not a lesser form of bipolar disorder, but includes high rates of disability and excess mortality similar to those encountered in type I bipolar disorder (Novick et al., 2010; Merikangas and Lamers, 2012).

Even milder forms of hypomanic features may arise in persons with recurrent depression, and have been considered part of a 'bipolar spectrum' of disorders related to bipolar II disorder (Angst et al., 2010). *Cyclothymia* is a form of bipolar disorder of limited severity whose diagnostic criteria are not well established and overlap those of type II bipolar disorder as well as certain personality disorders (Goodwin and Jamison, 2007). Antecedents, personality types or temperaments sometimes associated with bipolar disorder can be marked by sustained high energy, productivity, and social interaction ('hyperthymic' type) or long-term moodiness with moderate fluctuations between elevated and depressed mood and behavior ('cyclothymic' type).

Bipolar Depression

Bipolar disorder includes depressive episodes in forms ranging from profound inertia and withdrawal to severe, and sometimes psychotic major episodes, or sustained *dysthymia* of moderate intensity, as well as *dysphoric* episodes in which depressed mood is mixed with increased energy or irritable agitation (Baldessarini et al., 2010b). Characteristically, major episodes of bipolar depression present with psychomotor retardation or slowing of thought and activity with loss of interest in usual or pleasurable activities and impaired self-care. Along with a low level of energy, lassitude, and loss of sexual libido, abnormalities of sleep and appetite are usually found. These may include increased appetite and sleep (so-called 'atypical' features) or the anorexia and insomnia more typical of major depressive illnesses. Sluggish thinking, impaired concentration, and inability to make decisions are common, as well as feelings of worthlessness, guilt and self-blame may be present. Self-assessments in all forms of severe depression often are severely distorted, unrealistically negative and pessimistic and can alter recollections of previous phases of illness. Sometimes, somatic complaints such as migrainelike headaches, aching muscles or joints, gastrointestinal, respiratory, cardiac, and other somatic symptoms may be more prominent than psychic symptoms. Despair and hopelessness are common, and there is a greatly increased risk of suicide during depressive or more energized, dysphoric-agitated phases of the illness, with much less risk of suicide during hypomania or mania. Nevertheless, self-injuries and accidents can occur in all phases of the disorder.

Other Psychopathological Features

Bipolar disorder can present with mixed manic-depressive states that include both depressive and manic features at the same time or in rapid alternation. Both mania and hypomania can be associated with dysphoria and agitation, or may fluctuate rapidly within minutes or hours, between predominantly manic and depressive states ('emotional lability') and so can lead to the diagnosis of a bipolar 'mixed state.' Indeed, many, if not most episodes of mania are marked by emotional and behavioral lability and mixtures of depressive as well as excited features.

Bipolar disorder as well as severe major depressive disorder is associated with evidence of cognitive impairment that tends to be most prominent during acute episodes or illness, particularly depression, but may also be sustained between recurrences (Harvey et al., 2010). Long-term pharmacological treatment of bipolar disorder may contribute to reduced cognitive functioning, psychomotor slowing, and depressed mood. Such effects may not always be adequately evaluated and are usually considered to be minor (Baldessarini, 2013).

In addition, psychotic symptoms are found in perhaps three-quarters of bipolar disorder patients at some time. Bipolar disorder is, arguably, the most frequent form of idiopathic psychotic illness, exceeding even schizophrenia in prevalence (Goodwin and Jamison, 2007). Most commonly the delusions of bipolar disorder are paranoid, with either grandiose or persecutory themes (often pertaining to religious or other fame- or power-based exaggerations), particularly in manic or mixed episodes. Nihilistic or guilty delusions and other pessimistic exaggerations may occur in depressive phases of the illness. Self-referential misinterpretations of random events, as well as auditory hallucinations, may occur in manic and, less often, in depressive episodes. Psychotic features typically are congruent with the current dominant mood. Mood-incongruent delusions may involve impressions that thoughts are being externally controlled, inserted by, or broadcast to other persons. Some patients who have been diagnosed with bipolar disorder are later considered to have a *schizoaffective* disorder, as they show an excess of sustained, psychotic over affective features. They often become chronically ill with severe disability. Such disorders are currently considered as related to schizophrenia in current nosological systems, and their differentiation from severe bipolar disorder can be challenging (Pagel et al., 2013). Schizoaffective disorders also represent a challenge for the dualistic, Kraepelinian, division of severe or psychotic mental illnesses into a mainly mood-disordered episodic (manic-depressive) group and a more psychotic and chronic group (dementia præcox or schizophrenia). In general schizoaffective disorders remain inadequately defined or studied (Pagel et al., 2013; Salvatore et al., 2013a).

Co-Occurring Psychiatric Illnesses

Persons diagnosed with bipolar disorder often show features of other psychiatric syndromes, particularly major anxiety disorders (in about half of patients), including panic disorder, obsessive-compulsive disorder, or lesser forms of generalized

anxiety or particular phobias, and may meet contemporary, categorical diagnostic criteria for more than one disorder. It is uncertain whether such co-occurring conditions represent separate illnesses or are part of the spectrum of symptoms ('phenotype') of bipolar disorder. To some extent, the concept of 'comorbidity' may be an artifact of contemporary, categorical diagnostic systems (Vázquez et al., 2014).

In addition, abuse of alcohol or drugs occurs often in patients with bipolar disorder, and can severely complicate clinical management and worsen the overall prognosis (Goodwin and Jamison, 2007; Farren et al., 2012). Whether substance abuse is a contributing cause of bipolar disorder, or the disorder favors addictive behavior remains unresolved.

Psychodynamic Characteristics

Psychodynamic characterizations of bipolar disorder patients recognize prominent narcissistic features, lack of empathy, instability of interpersonal relationships, use of denial and activity defenses in hypomania, and guilt-driven self-aggressiveness. Mania has been considered an attempt to avoid or to compensate for depressive phases. Depression has been interpreted as a manifestation of self-aggression in response to the loss of a loved object (psychoanalytic perspective), as a consequence of learned helplessness after repeated, unavoidable, adverse experiences (developmental-behavioral model), or an expression of guilt for excesses during manic episodes (phenomenological view), or as an expression of negative self-evaluation activated by stress and learning (cognitive approach). Both polarities of bipolar disorder share common traits that may include emotional dependence, deficient awareness of internal emotional responses in oneself or others, and a lack of appreciation of differences between actual and idealized situations.

Diagnosis

The presence of at least one episode of mania is sufficient for a diagnosis of type I bipolar disorder, though most cases involve a series of manic and depressive recurrences over years of illness. Recurrences of clinical depression and hypomanic episodes (sometimes simultaneously) are considered to have type II bipolar disorder. Both types are recognized in the World Health Organization's *International Classification of Diseases* (ICD-10; WHO, 2000) and the American Psychiatric Association's *Diagnostic and Statistical Manual* (DSM-5; APA, 2013). The latter also recognizes 'rapid-cycling' bipolar disorder, with at least four episodes of mania or depression within 12 months of clinical assessment, as well as 'mixed-states' as a qualifying characterization that can be added to mania, hypomania, or bipolar depressive episodes (APA, 2013).

Sometimes mania arises in association with exposure to particular drugs or toxins, or with neurological or general medical disorders. Such responses are commonly associated with antidepressant treatment for depression or anxiety, or with stimulants for attention deficits, less commonly during treatment with anti-inflammatory corticosteroids, and rarely with use of quininelike antimalarial drugs, and may arise in dementia or following brain injury (Krauthammer and Klerman, 1978; Offidani et al., 2013).

Course of the Illness

The onset of bipolar disorder is often unrecognized as such, and several years may precede diagnosis and appropriate treatment. Many cases start in adolescence, and some before puberty when their distinction from attention or conduct disorders of childhood is often difficult, and they may arise from a background of depressive or anxiety disorders (Offidani et al., 2013; Salvatore et al., 2013b). More than half of bipolar cases present initially with an episode of mania or hypomania, particularly in men, whereas initial depressions are more common in women. Women also tend to have more type II bipolar illness and prominent depressive episodes, often with relatively frequent recurrences. Some cases present with recurrent depression, and mania or hypomania emerge later, sometimes during treatment with an antidepressant. Such cases are prevalent in adolescents and young (Baldessarini et al., 2013).

The natural duration of untreated episodes of mania or bipolar depression is about 6–9 months, with somewhat longer depressions, and approximately yearly recurrences, on average. With modern psychopharmacological treatments, acute symptomatic episodes of mania last about 1–2 months, and depression, 2–4 months, but full recovery may require several more months, and full functional recovery may not occur (Tohen et al., 2003). Without treatment, episodes of mania are slightly more frequent than depressive episodes, but total time in depression exceeds that in mania. This pattern currently may reflect generally inferior long-responses to available treatments for depressive versus manic phases of bipolar disorder (Baldessarini et al., 2010a,b).

Single episodes of mania with or without depressions, as well as single episodes of depression with one or more hypomanic or manic episodes occur in small proportions of cases. Instead, episodic recurrences are the rule and their course over years tends toward randomness among patients, without consistent progression toward shortening cycles, provided that analyses are adjusted for years of illness (Oepen et al., 2004; Baldessarini et al., 2012a). Although cycling frequency and patterns may be random among bipolar disorder patients, there is considerable predictability about the predominant types of recurrent episodes in individual patients, often with the same or similar polarity of initial episodes (mania predicting an excess of later mania, psychosis, and hypomania; depression predicting later depression; anxiety predicting later depression and anxiety; mixed-states predicting more depression or future mixed states of agitated dysphoria), as well as polarity-sequences similar to initial illness-cycles (Baldessarini et al., 2010a, 2014b). In addition, there is a generally worse long-term course and less responsiveness to mood-stabilizing treatments among bipolar disorder patients who usually present in depression and then cycle into mania (depression-mania-interval course-pattern), compared to those who usually present in mania and later become depressed (mania-depression-interval pattern) (Koukopoulos et al., 2013).

Pediatric-onset bipolar disorder remains a controversial topic, including its likely adult outcomes and its optimal and

safe treatment (Geller and DelBello, 2003). Such illnesses typically are marked by emotional turmoil and disturbances of behavior and sleep in childhood and involve highly unstable mood and behavior over periods of months or years. A pattern of discretely recurring episodes of mania and depression becomes established during adolescence and is usual in adults (Goodwin and Jamison, 2007). Long-term studies of outcomes among patients considered to have had 'juvenile-onset bipolar disorder' are emerging, and suggest that some may not progress to typical adult bipolar disorder (Geller et al., 2008; Baldessarini et al., 2013).

Mania beginning after age 60 years often follows a severe course, high recurrence rate, poor responsiveness to treatment, and a high mortality rate. Some such cases may be associated with early dementia (Dols et al., 2013a).

An unfavorable illness-course and inferior response to treatment are associated with rapid-cycling, usually defined as four or more recurrences of mania or depression within a single year, as is somewhat more common among women and persons with type II bipolar disorder (Tondo et al., 2003a). This pattern occurs in about 15% of cases, though only a fraction of such persons sustain high rates of recurrence over many years. An uncertain proportion of cases of bipolar disorder follow a rather consistent hemicircannual or *seasonal* course, commonly but not always, with depressions in fall or winter and manias in spring or summer (Faedda et al., 1993). This recurrence pattern is more likely with greater distance from the earth's equator, among women, and in younger persons.

A majority of bipolar disorder patients experience some degree of recovery between episodes of acute illness, and euthymic or stable periods often allow them to re-establish previous activities and relationships. Nevertheless, even with modern treatment, bipolar disorder can lead to sustained occupational and social dysfunction, particularly following youthful onset, psychotic symptoms, and early hospitalization (Tohen et al., 2003). Poorer outcomes tend to associate with very early or very late onset-age, frequent mixed episodes or psychotic features, severe and sustained depression, with a tendency toward sustained relatively rapid cycling, and as a consequence of inadequately treated episodes (Goodwin and Jamison, 2007; Farren et al., 2012; Swann et al., 2013). Long-term outcome in bipolar disorder reflects the secondary, adverse psychological and social consequences of the illness, associated stigmatization, and their often profound impact on self-esteem, independent functioning, and interpersonal relations.

Increased Mortality

Premature mortality is a strikingly common outcome in bipolar disorder, in part owing to its strong association with suicide. The *standardized mortality ratio* for suicide compared to the general population matched for age and sex may exceed 20:1 among bipolar disorder patients. More than one-third of bipolar disorder patients make at least one serious suicide attempt, and at least 10% of their deaths are ascribed to suicide indicating that the illness represents a nearly necessary, but not a sufficient, condition for suicide (Tondo et al., 2003b, 2007; Goodwin and Jamison, 2007; Manchia et al., 2013). Suicidal risks are similarly high in types I and II bipolar disorder (Novick et al., 2010). Suicide attempts have a particularly ominous implication in bipolar disorder (and in severe major depression), in that the *index of lethality* (ratio of attempts to fatalities) is probably less than 5:1, whereas in the general population the ratio is approximately 20:1, indicating greater lethality in bipolar disorder (Baldessarini et al., 2012a). The depressive and mixed phases of bipolar disorder carry the highest suicide risk, and account for at least three-quarters of all attempts and fatalities. Mixed-states with both agitated turmoil and dysphoria or depression are particularly risky (Swann et al., 2013). Risk of completed suicide in bipolar disorder is greater for men than women, whereas attempts are more frequent among women (Tondo et al., 2003b, 2007). Other risk factors include previous attempts, older age, abuse of alcohol or drugs, and probably a family history of psychiatric illness that includes suicide (Tondo et al., 2003b; Baldessarini et al., 2012a).

In addition to suicide, mortality rates are elevated in bipolar disorder owing to effects of risk-taking behaviors and to substance abuse leading to accidental deaths, medical complications of prolonged substance-abuse, and the impact of stress-sensitive cardiovascular, pulmonary, and endocrine disorders, in which mortality is perhaps three times higher than in the general population, and possibly greater than in many unipolar depressed patients (Tondo et al., 2007; Ösby et al., 2001). Owing to the large proportion of medically ill, elderly persons in the population, the number of deaths per year among bipolar disorder patients due to co-occurring medical disorders is very similar to the number associated with suicides, accidents and other violent forms of death (Ösby et al., 2001; Crump et al., 2013).

Epidemiology

Bipolar disorders have a lifetime prevalence ranging from at least 1.0% (for mania), to as many as 2–5% of the general population if type II and cyclothymic cases are included, and may approach 10% if bipolar spectrum cases with recurrent depression and very mild hypomania are included, and so may be similar to rates for nonbipolar major depressive disorders (Angst et al., 2010). The annual incidence of type I bipolar disorders is at least 0.05%. Women have a moderately excessive risk for bipolar disorder (sex ratio about 1.4:1) that is much less than in nonbipolar major depressive disorder (Goodwin and Jamison, 2007). The median age-at-onset is about 20 years (Baldessarini et al., 2012b). There have also been secular trends for all major mood disorders to be recognized more commonly and at younger onset-ages over the past century. However, the contributions of improved case finding, broadening conceptualizations of mood disorders, and the probable impact of substance abuse and other environmental factors to these trends are not well defined.

Biology

The risk of bipolar disorder, depression, psychosis or suicide in first-degree relatives of index cases of bipolar disorder is

approximately 20–25%. The same risk is found in fraternal twins, but it is about 70% in identical twins, leading to a monozygotic:dizygotic risk ratio of more than 3:1 (Goodwin and Jamison, 2007). Rare adoption studies carried out to evaluate the role of genetic versus environmental factors have found more affective illness and suicides among biological relatives of index cases of major affective disorders than in the adopting family (Goodwin and Jamison, 2007; Craddock and Sklar, 2013). Despite this substantial epidemiological evidence of a familial contribution to the risk of affective illness, a specific mode of inheritance, let alone a discrete genetic marker or molecular defect specific to bipolar disorder has yet to be identified (Bondy, 2011; Craddock and Sklar, 2013).

Other biological findings also are far from definitive (Kupferschmidt and Zakzanis, 2011; Yang, 2011; Cousins and Grunze, 2012). Structural and functional brain imaging techniques are receiving much attention, but the findings remain inconclusive, and risk lack of specificity in comparisons with other forms of severe mental illness. Older findings of changes in biochemical measurements of stress-sensitive neurotransmitters and neurohormones have proved nonspecific by diagnosis, or incidental to altered general metabolic activity and dependent on the state of being ill. There is also a tendency toward early appearance of the rapid-eye-movement phase of sleep in mania as well as in severe depression, with other alterations of ultradian or circadian biorhythms (Salvatore et al., 2013b). Some of these may persist even in euthymic or well intervals between episodes of acute illness, suggesting potential value as 'trait' markers (Yang, 2011; Salvatore et al., 2013b). Relative cerebral deficiency of the monoamine neurotransmitter serotonin has been associated with aggression and suicide, but this is not specific to bipolar disorder. Cognitive and other neuropsychological deficits can also be identified in bipolar disorder, and some may be sustained between acute episodes of illness (Vöhringer et al., 2013).

Clinical Management

Mania and severe episodes of bipolar depression require careful clinical management. Manic patients need protection if they show impulsive, hostile or excessively uninhibited, risky behavior, or if they refuse treatment. Bipolar disorder patients risk exploitation by others who may take advantage of their hypersexuality and inappropriate generosity in hypomanic states. In extreme cases, patients may need to be committed to specialized hospital units where they can be treated in structured, calm, secure settings that can provide expert care. Depressed patients may require hospitalization because of a high risk of suicide or inability to care for themselves. In both circumstances, early transfer to partial-hospital, day-treatment, or intensive outpatient treatment following brief hospitalization is often recommended.

Psychotherapeutic efforts are much less extensively evaluated in bipolar than in unipolar depressive disorders, in part reflecting traditional views that bipolar patients are often less able to accept their condition as a disorder requiring treatment. Nevertheless, psychotherapy methods developed and scientifically evaluated for depressive disorders may also have utility in bipolar disorder when acute symptoms are adequately controlled medically. These include interpersonal psychotherapy, based on improving coping strategies for social and interpersonal relationships. Cognitive-behavioral approaches attempt to modify irrational or exaggerated concepts by encouraging development of more flexible schemas, and rehearsal of new cognitive and behavioral responses. Psychoeducational and group-based or individual supportive treatments are advisable, and usually feasible with medication (Lolich et al., 2012).

Patients and their families also benefit from education about the illness, its treatment and expected course. Counseling is also useful to plan for the possible impact of the illness on career, financial planning, and family relations. Genetic counseling regarding risks to offspring can be offered. Also appropriate are recommendations to avoid pregnancy by women during treatment intended to be mood-stabilizing (especially with potentially teratogenic anticonvulsants), and it is necessary to discuss of maternal risks of abrupt discontinuation of treatment in anticipation of, or at the start of pregnancy, as well as anticipation of the high risk of recurrences early in pregnancy (especially of depressive and mixed states), and even greater risks in the postpartum period (including mania, psychosis, and risk of violence) without treatment (Viguera et al., 2007).

Treatment

Treatment of acute episodes of mania primarily involves antipsychotics or other central depressants (including some anticonvulsants, such as carbamazepine and divalproex) and potent sedatives such as lorazepam (Yildiz et al., 2011; Baldessarini, 2013).

Treatment of bipolar depression remains difficult and controversial (Baldessarini et al., 2010b). Particularly controversial are the effectiveness and safely of antidepressants for bipolar depression. Many experts believe that antidepressants are not only less effective but also dangerously destabilizing in bipolar disorder patients, short-term, and lacking in prophylactic effectiveness long-term (Pacchiarotti et al., 2013). However, emerging evidence suggests that many depressed bipolar disorder patients do respond to antidepressant treatment, especially if cases involving current agitation are avoided (Tondo et al., 2013; Vázquez et al., 2013). Agents with mood-stabilizing effects, such as lithium and lamotrigine, are probably ineffective in acute bipolar depression, and only partially protective long-term (Vázquez et al., 2013). Lithium and anticonvulsants, though not clearly more effective than antidepressants for bipolar depression, are associated with low risks of 'mood-switching' from bipolar depression to mania. Even during treatment with an antidepressant, the added risks may be quite small (5% or less), though risks of spontaneous switching into mania without exposure to mood-elevating drugs are quite high (10–15%) (Tondo et al., 2010). Such risks, including risk of inducing rapid-cycling lead many clinicians to avoid use of antidepressants to treat depressed bipolar disorder patients, especially those diagnosed with type I disorder or who have

switched into mania previously when exposed to a mood-elevating agent (Undurraga et al., 2012). It is widely assumed that combining antidepressants with antimanic agents or use of antidepressants other than tricyclics or venlafaxine given in low doses and briefly may limit risks of mood-switching, although these points remain unproved (Tondo et al., 2010; Pacchiarotti et al., 2013).

Despite current controversies about the value and safety of antidepressants for bipolar depression, they are among the most commonly prescribed drugs for bipolar disorder patients – probably reflecting strong efforts by patients to avoid this painful condition (Baldessarini et al., 2008). Modern antidepressants, including serotonin-reuptake inhibitors and bupropion are most commonly employed because of their far greater safety than tricyclic antidepressants on acute overdose with suicidal intent, as well as lesser risks of inducing mood-switches into mania. Electroconvulsive therapy may be a temporary alternative in severe cases and can be beneficial in both manic and depressive episodes. Available evidence supports the value of the modern antipsychotic agents quetiapine, lurasidone, and olanzapine (if combined with the antidepressant fluoxetine) for treatment of acute bipolar depression, and additional experimental agents are emerging (Pacchiarotti et al., 2013; Vázquez et al., 2013).

Since a key feature of bipolar disorder is recurrence of acute episodes, a principal aim of treatment is prevention of recurrences of both depression and mania. Lithium (as the carbonate or citrate) is the best established option for this purpose (Cade, 1949; Baldessarini, 2013). Lithium treatment also is the only psychiatric treatment with compelling evidence of reduction of suicidal behavior (Tondo et al., 2003b; Baldessarini et al., 2006; Yerevanian and Choi, 2013). Lithium treatment requires more than 1 week at safe doses to gain appreciable antimanic effects, and alone is usually insufficient as well as less rapidly effective than most antipsychotics and some anticonvulsants such as valproate and carbamazepine. Lithium has complex effects on interneuronal signal transduction and on other molecular regulatory events in nerve cells (Malhi et al., 2013). The principal value of lithium is for preventing, delaying, or lessening severity and duration of manic recurrences in a majority of bipolar disorder patients over many years, with lesser effects against recurrences of bipolar depression (Bauer et al., 2006; Baldessarini, 2013).

Alternative treatments compete strongly for the formerly leading position of lithium for the purpose of long-term mood-stabilization. These include the anticonvulsant lamotrigine (which is moderately effective against recurrences of bipolar depression, with little short- or long-term antimanic efficacy). Antimanic–anticonvulsants including valproate and carbamazepine (alone or with lithium) are also employed empirically in long-term treatment, even though such 'off-label' applications lack regulatory approval. In addition, modern antipsychotic agents, including quetiapine, aripiprazole, and olanzapine may have long-term benefits in bipolar disorder, although with the possible exception of quetiapine, best demonstrated for limiting recurrences of mania, whereas lurasidone appears to be selectively effective in acute bipolar depression.

Despite the growing number of treatment options, many bipolar disorder patients continue to experience some illness each year, including minor hypomania and dysthymia as well as major illness recurrences. In several long-term observational studies, including from first-episodes, bipolar disorder patients were ill approximately half of the time despite use of modern treatments aimed at mood-stabilization; moreover fully three-quarters of this unresolved morbidity was accounted for by depressive illness (Baldessarini et al., 2010a). Long-term effectiveness of lithium, anticonvulsants or antipsychotic drugs in bipolar disorder patients appears to be independent of past history, including the delay from illness-onset to the start of sustained treatment and the number of previous recurrences (Baldessarini et al., 2007).

Owing to its limited safety margin, daily minimum serum concentrations of lithium are monitored regularly to guide dosing, and are safe and effective in the range of 0.6 to 1.0 $mEq\,l^{-1}$, although levels of 0.60–0.75 $mEq\,l^{-1}$ are adequate for most patients and better tolerated than higher levels. Increased tremor, fatigue, dizziness, hyperreflexia, confusion, lethargy or convulsions indicate intoxication with lithium. Other adverse effects include tremor, polyuria, diarrhea, nausea, weight-gain, hypothyroidism, and occasional impairment of renal function with uremia. Lithium is also associated with Ebstein's teratogenic malformation of the cardiac tricuspid valve with septal defects (prevalence less than 1/1000), although such outcomes are uncommon, usually can be diagnosed prenatally, and are often repairable surgically (Giles and Bannigan, 2006). A serious problem of long-term treatment with lithium and most other psychotropic drugs is that abrupt or rapid discontinuation is often followed by temporarily greatly increased risk for recurrences of mania, depression, or suicidal behavior, even after years of effective treatment (Baldessarini et al., 1999; Bauer et al., 2006; Baldessarini, 2013).

Most antipsychotic drugs are rapidly effective in acute mania, and most modern antipsychotics have relatively low risks of many of the neurological adverse effects of first-generation neuroleptic drugs, but some (notably olanzapine and quetiapine) are very likely to induce weight-gain, with risks of 'metabolic syndrome' that can include type 2 diabetes mellitus, dyslipidemia, and hypertension – all major risk factors for potentially life-threatening cardiovascular disease (Centorrino et al., 2012; Czepielewski et al., 2013).

Adverse effects of anticonvulsants include headache, rashes and life-threatening Stevens-Johnson dermal and mucosal necrosis, especially with lamotrigine, as well as increasing the metabolic clearance of other drugs, especially by carbamazepine (Baldessarini, 2013). Some anticonvulsants including valproate and carbamazepine also have very high risks of severe teratogenic effects during pregnancy, including crippling and irreversible spina bifida, which can arise within the initial weeks of pregnancy; lamotrigine has been associated with mid-line facial clefts (Baldessarini 2013; Dols et al., 2013b). These risks require special care in the use of such drugs by women of child-bearing age. Concern about these risks is a common basis for discontinuing mood-stabilizing treatments, often with severe, adverse psychiatric consequences to pregnant women (Viguera et al., 2007; Baldessarini, 2013).

Birdsong and Vocal Learning During Development

Abstract

Songbirds are one of the few groups of organisms other than humans that learn sounds for vocal communication during development, and the neural substrate that controls vocal learning and behavior is highly localized, making these circuits amenable to experimental manipulation and analysis. The song system is a model one for studying the neural and hormonal bases of vocal learning, and for examining plasticity of structure and function in neural systems generally. Similarities between vocal learning in birds and humans suggest that many aspects of the learning process have evolved to meet demands imposed by vocal communication (Marler, 1976; Doupe and Kuhl, 1999). Therefore, an understanding of the mechanisms underlying vocal learning in songbirds may have immediate application to problems in human vocal learning. In this article, the author concentrates on what is known about neural and hormonal mechanisms of vocal learning in zebra finches (*Taeniopygia guttata*), a well-studied species in which juvenile males gradually learn to produce a specific vocal pattern during a sensitive period of development, and by adulthood are normally incapable of altering that pattern or learning new ones.

Songbirds are one of the few groups of organisms other than humans that learn sounds for vocal communication during development, and the neural substrate that controls vocal learning and behavior is highly localized, making these circuits amenable to experimental manipulation and analysis. The song system is a model one for studying the neural and hormonal bases of vocal learning, and for examining plasticity of structure and function in neural systems generally. Similarities between vocal learning in birds and humans suggest that many aspects of the learning process have evolved to meet demands imposed by vocal communication (Marler, 1976; Doupe and Kuhl, 1999). Therefore, an understanding of the mechanisms underlying vocal learning in songbirds may have immediate application to problems in human vocal learning. In this article, the author concentrates on what is known about neural and hormonal mechanisms of vocal learning in zebra finches (*Taeniopygia guttata*), a well-studied species in which juvenile males gradually learn to produce a specific vocal pattern during a sensitive period of development, and by adulthood are normally incapable of altering that pattern or learning new ones.

A Brain-Behavior System

Zebra finches learn the sounds used for vocal communication during a sensitive period of development. Specific auditory experience is necessary for vocal learning to proceed normally; juveniles must hear a 'tutor' song model (normally their father) from approximately 20–50 days of age in order to reproduce an accurate copy of that song later in development (e.g., Böhner, 1990). Zebra finches begin to produce their first song-related vocalizations around 30–35 days, and gradually refine their utterances until they achieve a close match to the external tutor sounds they have heard earlier (**Figure 1**). During this period of auditory-motor integration, birds must hear their own

Figure 1 A time line of zebra finch vocal development showing approximate timing of some aspects of song learning. Birds fledge from the nest around 20 days of age and start singing soon thereafter. They are dependent on their parents to feed them up until 35–40 days of age. The exact timing of auditory learning from an external model (tutor song) and reliance on auditory feedback of self-produced sounds are not completely known. Juvenile birds use auditory feedback to refine subsong until it matches the template of the tutor song. Once song learning is complete, adult birds also require auditory feedback to maintain production of stable, stereotyped song. Large-scale growth and regression of brain regions involved with vocal learning and behavior occurs during the sensitive period (see text).

vocalizations; auditory feedback is necessary for juvenile males to learn to adjust the motor patterns giving rise to vocal output so that the latter gradually comes to match the tutor song (Price, 1979). By 80–90 days, zebra finches are sexually mature and produce a stereotyped song pattern that is maintained without changes throughout adult life. Once a stereotyped song is produced, adults also rely on auditory feedback to maintain that stable song pattern (Nordeen and Nordeen, 1992). Surprisingly, although it has been known for many years that there is a sensitive period for hearing external auditory sounds during early stages of vocal learning, it is not known whether there is also a sensitive period for hearing self-produced sounds (i.e., for experiencing auditory feedback).

Song behavior is highly sexually dimorphic: normal adult females never sing, even if treated with testosterone (T). However, females treated with sex hormones soon after hatching produce male-typical songs as adults (Pohl-Apel, 1985; Simpson and Vicario, 1991). The behavioral dimorphism reflects a profound neural sex difference: the sizes of cortical song-control regions are several times larger in males than in females (Nottebohm and Arnold, 1976). The neural substrate for vocal learning and behavior is highly localized in males, comprising several interconnected brain regions (**Figure 2**) that are highly amenable to investigation of structure–function relationships. For example, high vocal center (HVC) and robust nucleus of the archistriatum (RA) are part of a direct efferent system linking the cortex with descending motor circuitry that activates vocal musculature, and lesions of this pathway disrupt stereotyped song behavior in adult males

Figure 2 A side view of adult male zebra finch brain showing a highly simplified schematic of the major circuits controlling vocal learning and behavior. HVC contains two separate populations of projection neurons, one sends axons to RA and the other to Area X. The HVC → RA pathway regulates production of already-learned songs in adult birds, and is assumed to be involved with later stages of song learning in juveniles. The HVC → X → DLM → LMAN → RA pathway is necessary for normal song production during early stages of vocal learning, but is clearly not on the main motor pathway for vocal behavior in older juveniles and adults (see text). RA projects to the motor neurons (nXIIts) that activate the vocal muscles. LMAN, lateral magnocellular nucleus of the anterior neostriatum; X, Area X of the avian basal ganglia; HVC, high vocal center; AUD, auditory cortex; RA, robust nucleus of the archistriatum; DLM, medial dorsolateral nucleus of the thalamus; nXIIts, tracheosyringeal portion of the hypoglossal nucleus.

(Nottebohm et al., 1976; Simpson and Vicario, 1990; Wild, 1997). The activity of HVC neurons in awake, singing birds correlates precisely with production of specific song syllables, indicating that the HVC → RA pathway is part of the online circuitry for producing learned vocal patterns in adult birds (McCasland and Konishi, 1981). Furthermore, the activity of RA neurons in singing birds correlates with subsyllabic elements of vocal production, whereas HVC neurons apparently encode larger chunks of information, indicating a hierarchical organization in the neural control of vocal behavior (Yu and Margoliash, 1996; Vu et al., 1994).

There is also a multirelay route from HVC to RA: a distinct population of neurons in HVC projects to Area X in the basal ganglia, which relays through the thalamic nucleus medial dorsolateral nucleus of the thalamus (DLM) to the cortical region lateral magnocellular nucleus of the anterior neostriatum (LMAN), which projects onto the same RA neurons that receive inputs from HVC. RA-projecting neurons in LMAN send an axon collateral to Area X, which creates a forebrain loop connecting X, DLM, and LMAN (Vates and Nottebohm, 1995). Lesions of the X → DLM → LMAN pathway have no effect on song production in adult birds, but profoundly disrupt song behavior in juveniles during early stages of vocal learning (Bottjer et al., 1984; Sohrabji et al., 1990; Scharff and Nottebohm, 1991). There is a dramatic decrease in the effectiveness of LMAN lesions in juvenile males around 55–60 days of age, which seems to correlate with the development of song as a motor pattern in the sense that the temporal sequence of notes becomes fairly regular at this point. These results suggest that LMAN circuitry is necessary for learning during early stages of vocal development, but may play no role in stereotyped vocal production. The decrease in the effectiveness of lesions within this pathway suggests a change in its function, whatever that may be. One possibility is that the function subserved by this circuit is either no longer important for vocal learning and production, or is taken over by other song-control circuits, such as the HVC → RA pathway. However, an alternative interpretation of the developmental decline in the ability of LMAN lesions to disrupt behavior is that the function of this pathway is conserved, but somehow masked or suppressed at later stages of vocal learning (see below). Either way, this pathway may be similar to mammalian basal ganglia pathways in terms of its involvement in motor aspects of learning, planning, and coordination of movement and motivation (cf Alexander, 1994; Graybiel et al., 1994; Bottjer and Johnson, 1997).

Steroid Hormones and Vocal Development

Much evidence suggests that sex hormones are involved in regulating one or more aspects of behavior during the sensitive period for song learning (Bottjer and Johnson, 1997). Blocking the action of androgens in juvenile zebra finches prevents the development of stereotyped vocal behavior (but has no effect in adults). That is, syllable order fails to become stereotyped in juvenile zebra finches that are castrated and treated with antiandrogens, such that the overall structure of song is unstable and abnormal. Interestingly, subsequent exposure to physiological levels of T in adulthood induces stereotyped song production over a period of weeks, suggesting that the final

stages of auditory-motor learning can be carried out in delayed fashion upon exposure to high levels of T. The enhanced behavioral and neural plasticity associated with the sensitive period for vocal learning appears to depend, at least in part, on the relatively low levels of circulating hormones that normally occur during early stages of juvenile development. In accord with the idea that reduced levels of plasma testosterone are actually necessary for normal song development, chronic exposure to normal adult levels of T during juvenile development severely impairs vocal learning in zebra finches. Juvenile males receiving systemic T exposure at the onset of vocal learning (20–40 days) develop fewer song syllables than controls, suggesting that the ability to memorize tutor syllables is impaired by exposure to adult levels of T during this interval. These data indicate that the proper timing and amount of exposure to hormones are important factors in the normal development of vocal behavior. Because many song-control neurons contain hormone receptors (particularly in HVC and LMAN), it is likely that T may exert direct effects on song-control circuitry to alter functional properties of neurons during vocal learning.

One possible speculation suggested by this pattern of results is that blocking the action of androgens extends a sensitive period for vocal learning, whereas normal exposure to rising titers of androgens closes one or more windows of opportunity for learning. This pattern of results has strong parallels to studies of human language acquisition, which have shown that the capacity for language learning decreases sharply following puberty (e.g., Johnson and Newport, 1989). It is also known that the sensitive period for song learning can be extended by rearing zebra finches in isolation. Although birds that remain isolated produce highly abnormal vocalizations, birds that are provided with tutors in adulthood can learn some song syllables long after the normal sensitive period has ended (Eales, 1987; Morrison and Nottebohm, 1993). Interestingly, juvenile birds that have been socially and acoustically isolated have abnormally low levels of T, although hormonal titers recover by the time birds reach late stages of song learning (Livingston et al., 2000). Thus the extended capacity for learning produced by isolation may be due to a prolonged period of low hormonal titers, although lack of experience may also be a contributing factor. It is possible that any conditions that prevent learning tend to keep the sensitive period open. This idea suggests the hypothesis that the loss of plasticity associated with the closing of the sensitive period is due to learning; if vocal learning is prevented then the sensitive period remains open.

Developmental Changes in Song-Control Nuclei: Growth and Regression

The neural substrate for song control undergoes large-scale morphological changes during the period of vocal learning in juvenile male zebra finches (Nordeen and Nordeen, 1997; Bottjer and Arnold, 1997). Substantial (e.g., threefold) changes in the overall size of song-control nuclei can include changes in neuron number and/or size and complexity of axon terminals and dendritic arbors. For example, HVC and RA grow substantially in males during song learning, more than doubling in volume, whereas LMAN shows substantial regression (**Figure 1**). Regression of LMAN correlates with the loss in effectiveness of LMAN lesions, whereas the growth of HVC and RA are consistent with the idea that the HVC → RA pathway assumes greater control of vocal behavior as song learning progresses. The profound growth and regression of song-control brain regions suggest highly dynamic roles for vocal circuitry in one or more aspects of song learning, and must be accompanied by substantial remodeling of synaptic connectivity. An interesting feature of these changes is that their occurrence during development is delayed relative to circuits that are not related to song control. Thus, the major neural scaffold controlling song behavior is created as song is being learned.

The gross changes in volume of brain regions observed during song learning suggested the possibility that experiential factors might play a role in inducing such morphological changes in the substrate for song, such that these large-scale changes actually reflect vocal learning. However, the volume and neuronal number of telencephalic song-control nuclei is the same in hearing and deaf birds, showing that auditory experience has no influence on regulation of neuron number, and that normal patterns of growth and regression occur even in birds that do not engage in normal song learning (Burek et al., 1991). This result indicates that gross morphological changes in song-control circuits are in fact *not* a product of the learning process, but rather may be prerequisite to learned changes in behavior. In accord with this idea, Brenowitz et al. (1995) demonstrated that tutoring two groups of marsh wrens with either many syllables or few syllables led to the development of large versus small learned song repertoires, respectively, although the size (and neuronal number) of HVC and RA in the two groups did not vary. However, within the group tutored with many syllables, only birds with a relatively large HVC learned large repertoires. Thus, a large HVC may be permissive for a larger vocal repertoire, but is clearly not a consequence of such. It seems likely that the basic neural scaffold underlying vocal learning is dependent on innate factors such as endogenous levels of hormones and cytokines (Johnson et al., 1997; Rasika et al., 1999). However, the idea that large-scale changes in song-control nuclei are a necessary prerequisite for vocal learning has not been tested directly (i.e., the occurrence of these changes during the sensitive period for vocal learning is correlational; cf Bottjer and Arnold, 1997).

Neural Signatures of Learning and Development

If large-scale patterns of growth and regression in the neural substrate for vocal learning are not a reflection of learning, then what changes in the brain signify learning and the close of the sensitive period? Several studies have described normative developmental changes that occur during the sensitive period, and may underlie specific aspects of the learning process. For example, the axonal projections of the DLM → LMAN → RA pathway show exuberant growth during early stages of song learning followed by pruning (Nixdorf-Bergweiler et al., 1995; Iyengar et al., 1999). In addition, NMDA (*N*-methyl-D-aspartate) receptors decrease in density within LMAN during song learning, and the duration of NMDA-R-mediated synaptic currents in individual LMAN neurons becomes significantly

shorter (Aamodt et al., 1995; Livingston and Mooney, 1997). These changes indicate that NMDA-R carry a greater proportion of the synaptic current in juveniles than adults. NMDA-R figure prominently in activity-dependent adjustment of synaptic connections because they require both a ligand (glutamate) and depolarization of the postsynaptic cell, they serve as molecular detectors of coincident pre- and postsynaptic activation and therefore provide a mechanism for Hebbian learning (e.g., Cline, 1991). Thus, it is possible that NMDA-R in LMAN neurons could detect correlated activity of auditory and motor aspects of song to reinforce synapses that correspond to the acoustic structure of tutor song. In general, highly precise patterns of synaptic connectivity as well as the behaviors they subserve are established during sensitive periods guided by activity-dependent mechanisms based on sensory experience (Knudsen, 1999), so it is therefore seems likely that experience-dependent synaptic rearrangements in song-control circuits, such as refinement of the DLM → LMAN → RA pathway, may underlie the emergence of specific vocal patterns.

If developmental changes in synaptic rearrangements and NMDA-R currents reflect learning, then one prediction is that they should be experience-dependent. This is at least partially true; isolation of juvenile birds to prolong the sensitive period (see above) does delay the shortening of NMDA-R currents, as well as loss of the modulatory subunit that gates the corresponding slow kinetics normally seen in juveniles (White et al., 1999; Singh et al., 2000). In addition, the number of dendritic spines on LMAN neurons decreases during song learning in normal birds, but remains high in age-matched birds that have been reared in isolation (Wallhaüsser-Franke et al., 1995), and the exuberant growth of the LMAN → RA connection is prolonged in birds that have been deafened or raised in white noise (Iyengar et al., 1999). However, isolation does not prevent these normative changes permanently. For example, although NMDA-R currents are longer in isolate-reared birds compared to normal birds at early stages of song learning, they recover to normal levels at later stages (Livingston et al., 2000). Thus, although LMAN neurons of isolate-reared birds seem to remain in a more juvenile state initially, they eventually achieve normal levels despite continued isolation. Furthermore, because isolated birds can learn some new syllables as adults, this pattern indicates that the enhanced NMDA-R currents seen in normal juveniles during the sensitive period are not necessary for at least some types of learning to occur. However, it is possible that the greater contribution of NMDA-R to synaptic currents in young birds could subserve some early aspect of learning that is necessary for later song development. For example, longer NMDA-R currents might enable young birds to learn an association between specific articulatory gestures and the vocal sounds they produce.

One way to assess this latter idea would be to prevent the longer NMDA-R currents that normally occur at the onset of the sensitive period. Exposing juvenile males to adult levels of testosterone starting at 20 days, severely disrupts vocal learning and causes premature shortening of NMDA-R currents as well as an accelerated loss of the slow modulatory subunit of the NMDA-R (White et al., 1999; Singh et al., 2000). This pattern is consistent with the idea that enhanced NMDA-R synaptic currents are necessary for some, perhaps unknown, aspects of vocal learning. The delay seen in several neural parameters caused by experiential and hormonal manipulations may provide neural correlates that contribute to the extended sensitive period for song learning in isolated zebra finches. Furthermore, the relative decrease in the contribution of NMDA-R currents could be responsible for closing one or more aspects of the sensitive period.

One particularly interesting neural signature of vocal learning is the development of auditory tuning in song-control neurons (Doupe and Solis, 1997; Margoliash, 1997). For example, LMAN neurons in adult birds that project to RA are selectively responsive to playback of each bird's own song, and this selectivity emerges at about 60 days of age, around the time when birds are beginning to produce a relatively stable song pattern and LMAN lesions are losing the ability to disrupt vocal behavior (Solis and Doupe, 1999; Rosen and Mooney, 2000). This correlation suggests that the development of auditory tuning coincides with a decreased role for LMAN neurons in vocal development, and is consistent with an idea raised above – namely that learning itself acts to curtail the sensitive period. Perhaps auditory selectivity of LMAN neurons reflects the fact that the bird has achieved a match to the tutor song (or developed their own individual template), such that LMAN no longer contributes actively to regulating the song pattern. Indeed, Solis and Doupe (2000) found that birds that were prevented from developing a good match to the tutor song (via damage to the vocal motor nerve) showed lower auditory selectivity in Area X than did birds that were able to mimic the tutor song. Thus, it seems as if the development of selectivity to bird's own song is dependent on learning, and perhaps a reflection of it. As indicated above, refinements of axonal connectivity such as that seen in the DLM → LMAN → RA pathway may represent an important neural signature of learning; remodeling of synaptic connections in this pathway may be necessary for the increased auditory selectivity of LMAN neurons.

Recent Findings

As indicated above, adult male zebra finches normally are incapable of altering their previously learned, stereotyped vocal pattern. This behavioral pattern correlates well with neural data showing that lesions of the X → DLM → LMAN pathway are effective only during a restricted period of vocal learning, and not in adult birds. These results encouraged hypotheses of vocal learning that stressed the idea that 'age-limited learners' such as zebra finches develop a fixed central motor program, and that the basal ganglia-thalamocortical circuit from Area X to DLM to LMAN is no longer able to regulate behavioral and neural plasticity in adult birds. However, traditional hypotheses have been challenged by recent data. (a) Exposing adult birds to delayed auditory feedback causes gradual deterioration of stable song, but original song patterns may be recovered when normal auditory feedback is restored (Leonardo and Konishi, 1999). (b) Although lesions of Area X and LMAN do not impair adult song production, the act of producing 'undirected' song (i.e., not directed to a female) induces strong expression of the immediate early gene *zenk* in X and LMAN of adult males (Jarvis et al., 1998), and multiunit activity recorded

in LMAN and Area X is consistently higher during production of undirected song (Hessler and Doupe, 1999). (c) Although lesions of LMAN in normal adults do not cause behavioral disruption, LMAN lesions in adult birds that are not producing a normal stereotyped song pattern do produce changes in song behavior, and prevent delayed learning from a tutor in isolate-reared birds (Morrison and Nottebohm, 1993). (d) Williams and Mehta (1999) demonstrated that vocal plasticity induced by injury to the vocal motor nerve (nXIIts) in adult birds is blocked by lesions of LMAN, and similarly Brainard and Doupe (2000) showed that LMAN lesions in adult deafened birds prevent gradual deterioration (i.e., the song remains stereotyped despite the absence of auditory feedback, suggesting that LMAN may monitor auditory feedback and respond if an error signal is detected; if LMAN is gone, the error signal produced by altered auditory feedback would not be detected in deafened birds).

In aggregate, this pattern of findings suggests that the X → DLM → LMAN pathway is not irrevocably 'shut down' in adults after vocal learning is complete, despite the fact that lesions of this pathway are ineffective in normal adults. Furthermore, one or more functions of this circuit may be 'reinvoked' by certain types of changes in learned song behavior. In addition, these results encourage the idea that adult zebra finches might be capable of new learning following the sensitive period, if appropriate conditions can be found (e.g., if the bird 'unlearns' his initial song pattern; Zevin et al., 2000). Loss of a stable vocal pattern may be a prerequisite to (re)inducing a greater degree of neural and behavioral plasticity in adulthood, perhaps by 'unmasking' an apparently latent function of LMAN circuitry that may be conserved in adult birds.

Conclusions and Questions

Vocal learning, like other developmentally acquired skills, is shaped by the interplay of innate factors and experiential influences during a sensitive period. The substantial growth and regression of song-control nuclei that occur during the period of vocal learning are not dependent on experience, and are likely regulated by innate factors that specify the amount of brain space allocated to vocal learning, thereby influencing how much can be learned (Nottebohm et al., 1981). Experience-independent specification of the basic neural scaffolding for vocal learning may also provide specific innate constraints on vocal learning, such as predispositions to hear or produce certain vocal sounds (Marler and Pickert, 1984; Marler and Sherman, 1985; cf Seidenberg, 1997). In addition, the fact that large-scale patterns of growth and regression occur as learned vocal behavior is being acquired may set temporal constraints on learning. Perhaps this is why humans, like songbirds, are much more adept at vocal learning as juveniles than as adults. If large-scale neural changes are necessary concomitants of vocal learning, then we must ask how experiential factors influence the fine scale of song-control circuitry during such changes. Is it possible that certain types of experience-dependent mechanisms, such as refinement of specific synaptic patterns, can operate only in the context of the overall growth and regression that occurs during song learning? Answers to such questions will begin to provide a better mechanistic understanding of sensitive periods in general.

Abtract

Conception from successful female ovulation and male insemination results in nine months' pregnancy and birth. The outcome of shorter gestation is premature birth of a low birthweight infant. Fertility regulation, or contraception, limits conception by male methods such as the condom or surgical vasectomy, and by females by use of the oral contraceptive pill, the female condom, or long-term breastfeeding of the previous infant. Prenatal care refers to learning how to maintain health and prepare for the birth of a healthy infant.

An anthropology of birth is based on the common human experiences of insemination, conception, pregnancy, and birth of an infant. Characteristic of the human species and central to the origins of culture are the immaturity of the newborn human and its long-term dependence on caretakers for survival. These experiences exist in every society, but details vary in different cultural environments.

Cultural Anthropological Perspectives

Anthropological perspectives on birth are concerned with the context, variety, and complexity of reproductive life, modes of caring for a newborn infant, and cultural factors including rules for behavior that are learned, shared, and transmitted within families and cultural groups. There is cross-cultural variation among societies during these universal human processes. Because birth and recruitment to society are important to all human groups, customs and rules surround fertility behavior in all societies.

The influence of culture appears in definitions, for example, of which individuals may become parents (maternal age or married status), or the beginning of life (the point of conception, pregnancy to a viable birthweight, or delivery of a live infant). Throughout history and across cultures, certain variations have occurred in the definition of when life begins – whether it is at birth, or from motion or other indication of consciousness of an infant, or at a formal tenth day ceremony. Naming an infant provides a universal identification of the beginning of social life. Membership in society is defined and protected by both rules and traditions of social behavior. For example, international differences in mate selection include monogamy, or single partners, in most of the Christian Western world, and polygamy, or multiple wives in religious groups such as Mormons in the United States, or in some Islamic countries.

Differences occur also in sexual behavior, timing of pregnancy, and reproduction of society over time. It is the basis of identity, including how many people will be members of each society. The concept of 'legitimacy' refers to the acceptability of infants born to married mothers in most societies. 'Illegitimacy' refers to birth to an unmarried mother. Despite the language of legality, this is not generally an issue of law, but of social or religious acceptability.

Additional international and intercultural differences are discussed in the following sections, including fertility and fertility regulation, prenatal care, a comparative view of birth rates in different countries (Table 1), infant and under 5 child mortality (Table 2), and finally, the impact of the modern international infectious disease of HIV (human immunodeficiency virus, Table 3).

Fertility

Fertility refers to the capability of reproduction in the human species from sexual relations of male and female to conception and pregnancy in the female. Sex and social continuity are of concern in all societies. This concern is a part of the ancient and universal desire to bring order to membership in society as well as the behavior of individual members. 'Infertility' of either partner indicates an incapacity to reproduce.

Pregnancy occurs as a result of the connection of male sperm to female ovum initiating cell division leading to conception and beginning development of an embryo, until around the third month of gestation when it begins to develop body structures recognizable as human, and enters the fetal

United States	0.76	820

stage. Cells differentiate and the fetus then grows and develops the human form of an infant.

Gestation is the period of intrauterine development. Human variation occurs in the length of gestation for live birth. The biologically expectable period of gestation is around nine months of pregnancy. However, there can be differences in the timing, location, and length of the birth process. In some societies infants are delivered by a midwife or nurse, or a birth specialist either at home, or in the institutional setting of a hospital or nursing home. In modern urban societies, delivery of an infant is usually conducted in a hospital by a nurse or a physician specializing in obstetrics. Even here, however, there are significant cultural differences. For example, in urban areas, the surgical procedure of caesarean section is used for an impeded delivery, or for selective timing of birth.

In developed countries medical care may include prenatal care with a medical specialist in obstetrics or a nurse practitioner in a professional medical environment. In many areas of the world, reproductive health and training for motherhood are carried out by a nurse midwife or an experienced female family member, although there is increasing professionalization of birth attendants internationally. Attention to the process of gestation is perceived as important to the quality of life of the potential human being in all societies.

Fertility Regulation

Fertility regulation refers to intentional methods of avoidance of pregnancy used by either male or female. There have been methods of fertility regulation at least as far back as the beginnings of recorded history, as families have sought to control the number and timing of births. Male methods of family planning can range from a barrier method such as the condom, or withdrawal, or the surgical procedure of vasectomy. Female methods include the oral contraceptive pill or the barrier method of the female condom. Extended breastfeeding of the previous infant has long been known to suppress ovulation and enable spacing between births.

Social concerns regarding birth and reproduction vary internationally, with age, ethnic identity, or religion. Cultural factors, such as assuring virginity of marriageable females in some societies, religious opposition to fertility regulation in others, or in a few societies, female genital surgery for removal of the clitoris to reduce female enjoyment of sexual relations, have an impact on quality of life as well as reproductive capacity.

Ending unwanted pregnancy is one of the most contentious issues of reproduction. It may be terminated by induced clinical abortion in those countries where it is legal and medically provided. The psycho-social effects of unwantedness of a newborn infant are difficult to measure, but outcomes appear consistently negative in terms of later parental disinterest, child abuse, or abandonment. However, while clinical abortion is legal in such countries as Sweden, Japan, or the United States, it is illegal in most Muslim and Catholic areas. In these countries, family planning is more likely to include abstinence during the expectable time of ovulation (sometimes difficult to determine), and birth rates may be comparatively higher.

Prenatal Care

Most developed societies have some form of preparation for birth. The importance of prenatal care is in testing for health of the fetus, and in teaching the pregnant woman how to maintain the best possible health for herself and her expected infant. This includes protective health care, measuring regular weight gain, providing training for the birth process, and social support.

An important component is also prevention of behaviors detrimental to infant development. For example, prenatal smoking, alcohol and drug use, or starvation to limit weight gain, can all have damaging effects on the developing fetus. These can range from decreased blood flow to the fetus from smoking to fetal alcohol syndrome (FAS), which can result in abnormal physical or mental development (Espy et al., 2000). As risks from these behaviors have become better known over the last several decades, preventing risks of learning impairment in the resulting child is an important component of effective prenatal care before birth (Newman, 1996).

Premature Birth

Not all pregnancies continue to a viable birth. Loss can occur at any time. Abortion refers to expulsion of a malformed or

incompletely developed embryo within the first three months of gestation. Later loss can result from fetal death. For example, if loss occurs in the first weeks of pregnancy, it is considered a 'miscarriage' of a non-viable fetus. Early delivery of a viable infant at a birth weight of 2500g (about 5.5 16) can happen as early as seven months gestation, and is termed 'low birth weight.' 'Very low birth weight' refers to the infant born around 1500 g.

In developed and industrialized countries, extensive efforts are undertaken to ensure survival of the lowest birth weight infants. A viable low birth weight infant in developed countries is kept at a neonatal intensive care nursery in an incubator for clear observation, to maintain body heat, and to provide oxygen, if necessary to breathing, as well as to enable constant surveillance by special care staff. The purpose of enclosure in all countries is to keep the premature infant safe from infection. In developing countries without intensive care technology, such babies are seen as likely to suffer mental and physical limitations, and may not be given special care so that family and community resources can be focused on those infants perceived as more viable.

Birth Rate

Birth rates differ from country to country based on religion, cultural expectation, issues such as female participation in the workforce, or religious and political views of fertility limitation through birth control. It can also be influenced by political programs such as China's 'one child family' policy previously undertaken by the nation with the highest population in the world.

Table 1 indicates total population for 12 nations and the birth rate, or births per woman, for each country.

Infant Mortality

Infant mortality refers to death in the first year of life. While it has lessened worldwide in the twentieth century, the rates vary in different countries, ranging from 5 per 1000 live births in developed countries such as Australia and France, to as many as 76 per 1000 live births in Nigeria. Rates of Under 5 Child Mortality, while higher, are comparable nationally. Table 2 compares Infant and under 5 child mortality in 12 countries.

While infant mortality can occur from prenatal causes, or in the process of delivery, it can also occur through accident or by endemic infectious disease later within the first year of life.

In many areas of the world, fertility regulation and birth control methods have been used to increase the time between births and enable optimum developmental opportunity for each infant born. Exceptions occur in those countries where fertility regulation is forbidden by religious law. Birth spacing is accomplished in some countries by later marriage and in some by abstinence during the fertile period of ovulation.

Sexually Transmitted Disease

The most pervasive sexually transmitted diseases in the world have been syphilis, gonorrhea, and chlamydia. However, a powerful new influence on the culture of pregnancy and birth is the spread of the new infectious disease of the modern world, human immunodeficiency virus, or HIV infection, identified in 1980. While HIV can be transmitted by sharing needles among drug users, it can be transmitted sexually to both males and females. It is also transmitted from mother to infant prenatally, during delivery, or postnatally through breast feeding (WHO and UNAIDS, 1998). This has had a devastating effect internationally on the number of infants born with HIV infection or being infected within the first year of life. While the prevalence of HIV differs geographically, and in many countries is less than 1 percent, the rate in some African countries is higher, ranging from 4 percent to 12 percent, as indicated in Table 3.

The fear of becoming HIV positive is beginning in some countries to change behavior toward careful choice of sexual partners, and using barrier methods of protection. The failure to change in other areas has led to devastating epidemics of HIV.

Conclusion

Anthropological perspectives on birth enable cross- cultural comparison of healthy birth practices and effective family planning methods based on cultural acceptability. Effective fertility regulation and prenatal care enable continuing reproductive health. Cultural variation in reproductive rights, values, and education demonstrate differences in fertility, contraceptive use, and birth practices, as well as expected family size internationally.

Bleuler, Eugen (1857–1939)

Paul Hoff, Psychiatric University Hospital, Zurich, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Swiss psychiatrist Eugen Bleuler (1857–1939) became known worldwide through his theory of the 'group of schizophrenias' and their psychopathological formation, a conception that differed markedly from Emil Kraepelin's prognostically pessimistic 'dementia praecox theory' and that incorporated specifically psychoanalytical elements. Bleuler sought an understanding of psychosis that, while fully acknowledging the biological determinants, brought in the individual psychological, social, and anthropological dimension. Furthermore, he outlined a natural philosophy in his later work that was to a large extent independent of contemporary philosophical trends, but that was, however, barely taken up by either psychiatry or philosophy.

Eugen Bleuler is a central figure in the history of European psychiatry. His importance is founded on the fact that he proposed and practiced a critically mediating link between two basic psychiatric positions that stood at two controversially opposite poles at the beginning of the twentieth century (and that still do in part up to the present day) – that is, generally speaking, the tension between objective and subjective methods in clinical assessment as well as in research, or, more specifically, the psychoanalytical depth psychological school on the one hand, which was situated predominantly outside the universities, and academic psychiatry on the other, which was oriented principally toward the descriptive somatic approach. In this respect Eugen Bleuler – to put it in layman's terms – stood, as far as his basic psychiatric conviction was concerned, between the two similarly aged exponents of the aforementioned competing approaches, namely, Sigmund Freud (*see* Freud, Sigmund (1856–1939)) and Emil Kraepelin (*see* Kraepelin, Emil (1856–1926)) (Hell et al., 2001; Hoff, 2009).

Born in Zollikon, near Zurich, on 30 April 1857, Bleuler came from an old-established Swiss farming family on both his father's and his mother's side. After completing his medical studies between 1875 and 1881, he worked first as an intern at the psychiatric clinic Waldau, near Bern. Study visits took him to Paris (with Charcot and Magnan) and to Munich (with von Gudden, who had been the first director of the Psychiatric University Hospital in Zurich, named the 'Burghölzli,' from 1870 to 1872). In 1885, Bleuler went to work with Forel at the Zurich 'Burghölzli' clinic, which had been founded in 1870, only to be appointed director of the Psychiatric Hospital Rheinau in the canton of Zurich the following year, a position which he held for 12 years, that is, until 1898. The professional position that followed also covered an unusually long period of time and brought with it more far-reaching repercussions and to a large extent had a formative influence on the way Bleuler was to conceive the whole field of psychiatry. He took over the chair in psychiatry at the University of Zurich in 1898, succeeding Auguste Forel (1848–1931), a position that was attached to the directorship of the 'Burghölzli.' Bleuler held this position for almost three decades until 1927.

At the end of his academic life – he was at that time also the Rector of the University of Zurich – he was said, in an account cited by the Swiss psychiatrist J. Klaesi, to have remarked, not without a hint of maliciousness, "that the state forces one to be an old man at 72" (Klaesi, 1970). Eugen Bleuler died in Zollikon at 83 years old on 15 July 1939.

Bleuler's work is characterized by its tireless attempt, influenced by a strong sense of respect for the individual patient, to approach the enigma of psychotic illnesses on as many levels as possible, while at the same time taking into consideration general or normal psychological findings. On the one hand, he wanted to avoid making any one-sided dogmatic assertions, such as in the sense of Karl Jaspers' polemic term 'brain mythologies,' which, with no further reflection, identified psychic phenomena with neurobiological processes along ingenuously materialistic lines. On the other hand, Bleuler was concerned with regarding the psychotic person *not only* as ill, as deviant, or as disturbed, but rather he directed his attention toward the fundamental comparability to healthy mental life, a standpoint that interested him above all because of the possibility for its therapeutic exploitation. This did not mean, however, that Bleuler in any way placed little value on the then-prevailing 'brain pathological' – in twenty-first century terminology, neurobiological – school of thought and the research approaches arising from it. On the contrary, like the vast majority of contemporary psychiatrists, he too was convinced that the brain function in the etiology and pathogenesis of endogenously psychotic illnesses – predominantly, therefore, schizophrenic and (bipolar) affective disorders – played a decisive role. Unlike the many 'simplifiers,' however, Bleuler always insisted that it was of great importance for the handling of patients, for the diagnosis, and above all for the therapy to *understand* the clinical picture and each individual, concrete symptom, independent of the suspected etiology.

Bleuler's handling of the basic concepts of association theory was not unified and hence was liable to give rise to misunderstandings and controversial statements. On the one hand, he repeatedly took up a clear position against the 'association psychology' in the narrow sense advocated earlier in the nineteenth century, in which (healthy as well as ill) human mental life was merely the sum total of individual intellectual associations prompted by sensory perception. Against this, he set an affective psychology that aimed to comprehend the personality in its individual totality, but that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61009-7

nonetheless was coupled substantially with elements from association psychology in the field of the schizophrenias. Indeed, not only did Bleuler see no contradiction in this, he even saw it as objectively necessary. It was here that the (then as now) topical controversy surrounding the quantifying scientific *explanation* and the interpretative humanistic *understanding* of mental and, in particular, psychotic manifestations arose. Bleuler also attempted in this context to overcome a rigid distinction between the two approaches, quite unlike Karl Jaspers, who strongly criticized him over this on several occasions (e.g., in Jaspers, 1923).

Unlike most of his university colleagues in his field, Bleuler saw in general terms *no* fundamental contradiction between (explanatory) brain research in the broadest sense and the interpretative access to the psychotic of depth psychology, which at that time was almost exclusively advocated for by the still-young Sigmund Freud. On the contrary, Freud's theory seemed to Bleuler to be virtually predestined for critical implementation into clinical psychiatry. For Freud himself, who fought a lifelong struggle to achieve 'academic' recognition for his theory, such a competent and influential researcher like Bleuler naturally took on a particularly great importance. Bleuler, however, emphasized the aspect of the *critical* adoption of psychoanalysis already mentioned so much over the years that it led to a rift (Bleuler, 1913; Dalzell, 2007; Küchenhoff, 2001). Much has been written about the escalating debate between Freud and his particularly creative and original disciples, such as Carl Gustav Jung (*see* Jung, Carl Gustav (1875–1961)) or Alfred Adler. It is less well known that Eugen Bleuler also must be mentioned in this connection. The psychiatry historians Alexander and Selesnick (1969) went so far as to call him the 'first victim' of this controversy, as Bleuler resigned from the International Psychoanalytic Society in 1910 because of his discontent at its, in his view, authoritarian style of leadership. The fundamental importance of the depth psychology approach for psychiatry was for him in no way diminished because of this (Küchenhoff, 2009; Wieser, 2001). Scherbaum (1992) pointed out the paradoxical situation that Bleuler was 'too psychoanalytical' for academic colleagues in his field, whereas the psychoanalysts for their part viewed him as being too critical, even 'disloyal,' and he posed the question of whether Bleuler's understanding of psychoanalysis might not also have been shaped by the same 'scientistic self-misconception,' which Habermas (1979) had observed in Freud himself.

One book chapter was of decisive importance for the development of *clinical psychiatry*, a chapter of 420 pages that Bleuler (1911) had written for the *Handbuch der Psychiatrie (Handbook of Psychiatry)*, edited by Gustav Aschaffenburg, entitled *Dementia praecox oder Gruppe der Schizophrenien* (1911; *Dementia praecox, or the Group of Schizophrenias)* (Bleuler and Bleuler, 1986; Kaplan, 2008; Kuhn, 2004; Scharfetter, 2001, 2006; Stotz-Ingenlath, 2000). The agenda was already set out in its title. Unlike Kraepelin, who was searching for 'natural disease units' and through whose influential textbook the concept of 'dementia praecox' had become both popular and influential in the German-speaking world (Hoff, 1994), Bleuler did not speak of schizophrenia as a *single* unit, but rather he spoke of the *group* of schizophrenias. He was concerned, however, with the question of which characteristics the otherwise-heterogeneous schizophrenic patients had in common. Bleuler was describing first and foremost *psychopathological* phenomena and was avoiding any all-too-narrow (and speculative) analogies to the brain function.

Two psychopathological distinctions that Bleuler introduced are important with regard to schizophrenic psychoses and frequently are confused: the basic and accessory symptoms on the one hand, and the primary and secondary symptoms on the other. *Basic symptoms* were, according to Bleuler, peculiar to every schizophrenic disease process, independent of its other clinical manifestation. Among these he counted disturbed associative processes (a kind of dissociation relating not only to formal thought processes but also to all other mental functions – hence the term *schizo*phrenia meaning *splitting/dissociation* of mental processes), schizophrenic autism (not to be confused with the syndrome of the same name in child and adolescent psychiatry), ambivalence (a volitional disorder), and various types of affective disturbances. *Accessory*, that is, not necessarily existing and also frequently observed in nonschizophrenic and above all exogenous psychoses, meant symptoms such as hallucinations, delusion, or catatonic states. Although this differentiation is still of great heuristic value for psychopathological research in the twenty-first century, the differentiation between the *primary symptoms* – which result directly from the suspected organic disease process – and the *secondary symptoms* – which constitute a subjective psychological reaction to the illness by the person affected – has lost considerable importance.

In contrast to the (as the term implies) prognostically pessimistic concept of 'dementia praecox,' such as in Kraepelin's work, Bleuler constantly stressed that there were also benign schizophrenic courses – and by no means only as an exception – that after one or more episodes turned into an extensive or complete recovery.

The *Lehrbuch der Psychiatrie* (*Textbook of Psychiatry*), which first appeared in 1916, achieved a virtually legendary reputation. In this work, Bleuler (1916) put forward his deeply personal view of this field in a systematically, vividly, and clinically oriented manner. He had worked 5 years on this book. It went through many editions, for which he himself took on the task of updating as necessary up to and including the sixth edition. After his death (1939), his son Manfred Bleuler took over the task.

Bleuler's (1925) writings on general psychology and philosophy have, on the other hand, all but been forgotten in the twenty-first century. In his later work – such as in the work *Die Psychoide als Prinzip der organischen Entwicklung* (1925; *Psychoids as a Principle of Organic Development*) – he attempted to develop a comprehensive natural philosophical concept that, however, was not adopted on any great scale at the time. His basic idea of a memory that was independent of conscious processes and did not only refer to the individual person but also – and thus in a way an evolutionary biological perspective – to the whole species ('Mneme'; Bleuler, 1934) was, in its idiosyncratic embracing of biogenetic vitalistic ideas of the late nineteenth century, of central importance for Bleuler's whole scientific understanding. Although Bleuler considered inappropriate the classification of his (later) work as 'vitalistic,' from the point of view of the history of twenty-first century psychiatry, the parallels are unmistakable. This is true in

particular if one looks at Bleuler's objective of a comprehensive 'science of life,' which did not separate the categories of physical, biological, mental, and even social phenomena from each other, but rather sought to understand them as scientifically equal forms to express a single integrative (life) principle (Möller and Hell, 2000; Möller, 2001). A weakening or even lifting of the aforementioned categorical dividing lines (although not *this* particular way) is a highly topical subject in psychiatric research, which, indeed, appears less and less willing to maintain the classical differentiation of 'organic' and 'endogenous' as well as 'psychogenous' illnesses.

The approaches in his later work, irritating and speculative as they seem to twenty-first century readers, may be regarded a critical part of Bleuler's thinking. Yet another aspect is even more problematic: As many contemporary academic psychiatrists, Bleuler – especially regarding questions of forensic psychiatry that are also in his work – repeatedly referred to the concept of 'degeneration' (Entartung). Even his explicit awareness that the term 'degeneration' was vague and scientifically questionable did not prevent him from discussing and applying it in several contexts. A considerable number of research activities addressed this field in the past decades, often focusing on classical authors like Emil Kraepelin, Richard von Krafft-Ebing, or Eugen Bleuler (Pick, 1989; Hermle, 1986; Hoff, 2008).

In view of the whole picture, however, Eugen Bleuler was one of the most original and consistent psychiatric clinicians and researchers of his time. His thought is also of interest to current research into psychosis and has been receiving increased attention in recent literature (Hoff, 2010, 2012; Moskowitz and Heim, 2011). What is particularly gratifying about this is the fact that research into the history of psychiatry has turned away extensively from the bad habit, which one often came across in the early years, of uncritically hagiographic and therefore unscientific excessiveness from eminent advocates in the field. It now is concerning itself discernibly with a comprehensive understanding of the history of the field supported by the original literature and other sources, and is embedded in contexts from social history and the history of ideas.

Abstract

The French historian Marc Bloch (1886–1944) is one of the authors most frequently cited by those working in contemporary historical disciplines around the world. This immense influence is founded on both scholarly and biographical grounds. As one of the founders, together with Lucien Febvre, of the journal '*Annales d'histoire économique et sociale*' in 1929, and as a pioneer in the field of the history of society and mentality, a historical theoretician, and a critical intellectual who was executed by the Gestapo in 1944, Bloch has become an inspiration and model for generations of researchers working in a diverse range of scientific fields and from a variety of different political perspectives.

The French historian Marc Bloch is one of the authors most frequently cited by those working in contemporary historical disciplines around the world. This immense influence is founded on both scholarly and biographical grounds. As one of the founders of the field of the history of society and mentality, a historical theoretician, and a critical intellectual who was executed by the Gestapo in 1944, Bloch has become an inspiration and model for generations of researchers working in a diverse range of scientific fields and from a variety of different political perspectives.

Marc Bloch was born in Lyon on 6 July 1886 in a family of practicing Jews of Alsatian heritage. Bloch himself was an agnostic, and in his final will and testament he explicitly requested a secular funeral. Because his father was Professor for Roman History at the Sorbonne, Bloch grew up in Paris, where he visited the elite secondary school *Louis-le-Grand*. From 1904 to 1908, he studied history and geography at the *École Normale Supérieure* in Paris; following this period he spent two semesters in Berlin and Leipzig, where he attended lectures by scholars such as Gustav Schmoller, Karl Bücher, and Karl Lamprecht. From 1909 to 1912, he was the recipient of a *Fondation Thiers* scholarship, before becoming a teacher at secondary schools in Montpellier and Amiens. Bloch fought on the front as an enlisted soldier in World War I, and in the course of being repeatedly wounded in action and decorated for his service he was promoted to the rank of captain. In 1919, he married and was appointed lecturer for medieval history at the newly founded French University of Strasbourg. In 1921, he was appointed associate professor, and in 1927, he received his full professorship. In 1929, together with his Strasbourg colleague Lucien Febvre (1878–1956), Bloch founded the journal *Annales d'histoire économique et sociale*, which rapidly grew to become a widely influential forum for innovative historiography. In 1936, after several unsuccessful attempts to apply for a position in Paris, Bloch was granted a Sorbonne professorship in economic history. Immediately following the outbreak of World War II, he volunteered for military service to defend his homeland against Nazi Germany. As an officer sent to reinforce the First Army, he experienced both the anticipation of the '*Sitzkrieg*' and then the unexpectedness of the '*Blitzkrieg*' in the French coastal canal region. Like thousands of other French soldiers, Bloch was rescued from Dunkirk in June of 1940 in the emergency evacuation across the channel. From England, he returned immediately to France, where he was able to avoid imprisonment. Because Nazi law prohibited him from reassuming his teaching position at the Sorbonne, the Vichy government sent him to rejoin the faculty of the University of Strasbourg, which had been relocated to Clermont-Ferrand. At the same time, Bloch sought, and eventually attained, an appointment at the New School of Social Research in New York. Because of the complicated provisions for obtaining a visa, however, he would have been compelled to leave behind most of his family in France – a condition Bloch, the father of six children, was entirely unwilling to accept. In December of 1940, Bloch was barred from government service by the 'Jewish Statute,' only to be exempted several weeks later along with a number of other prominent Jewish scholars, and allowed to reassume his teaching duties. For the sake of his wife's health, Bloch applied a year later for a transfer to Montpellier, even though this meant that he would no longer be permitted to hold public lectures. It was at this point in time that Bloch's active involvement in the *Résistance* began. Following the occupation of the Vichy zone by the German army in November 1942, Bloch left Montpellier with his family for his countryside home near Guéret in the Creuse district of France. From this time on he worked and lived for the clandestine resistance. Operating under pseudonyms like 'Chevreuse,' 'Arpajon,' and 'Narbonne' he belonged to the masterminds of the left-wing '*Franc-Tireur*' movement in Southern France. In 1943, he moved to Lyon, where he belonged to the regional leadership of the '*Mouvements Unis de la Résistance*.' On 8 March 1944, Bloch was arrested by the Gestapo and brutally tortured before being thrown in prison. On 16 June, several days after the Allied troops landed at Normandy, Bloch and 29 other prisoners were taken to a field on the outskirts of Lyon and shot.

The thematic emphasis of Bloch's scholarly production lies in the social and economic history of the medieval period. Although, Bloch was initially concerned primarily with the topic of serfdom, in the early 1920s he began to devote his attention to what appeared to be a highly specific question in the field of political theology: namely the issue of the widespread belief in feudal France and England in the healing power of the king; in particular, when he laid his 'holy hands' upon the sick who had gathered before the cathedral following the coronation ceremony. This anthropological approach,

however, so clearly inspired by Durkheim's sociology of religion, was one Bloch would only use intermittently in later years. Instead, he turned his focus to a comparative historiography of (1) European agricultural structures and (2) societal structures that spanned the period from late antiquity to early modern times. As he wrote in his 1934 application for a teaching position at the *Collège de France*, he no longer considered himself to be first and foremost a 'medievalist,' but rather a general historian of 'European societies.' His two-volume work *Feudal Society* (1939–40) can be understood as an exemplary attempt at putting this perspective of a '*histoire totale*' into practice. In what amounted to an intellectual testament, Bloch himself summed up his book as follows: "I have given an example of something […] that I chose to call 'the dissection of a social structure.' In the course of the development of Western society there was a phase, which we call feudal society, which had a certain social tone. It was this tone that I wanted to investigate. […] Furthermore, I have attempted to bring into play in a European context the multifarious experiences, which the comparative method allows us to grasp. If my work is truly original in one regard, then in my opinion its originality lies in both of these efforts: structural analysis and the incorporation of comparative experiences" (*Cahiers Marc Bloch*, No. 2, 1995, p. 16).

Bloch's originality lies indeed in this 'structural' and comparative approach, but also in the manner in which he conducts his scholarly interventions. Precisely because he took the approach of Durkheim disciples, such as François Simiand, seriously, who in their work had critically engaged the traditional praxis of political history, Bloch had been confronted with the necessity of making a fundamental change in the theory and practice of historiography. In countless essays and reviews he called not only for a new, interdisciplinary, and internationally oriented historiography, which would address itself to new themes by means of new methods, but also for new ways of educating historians and new forms of communication within the historian's guild. An important instrument, a sort of editorial 'lever,' in his efforts to this end was the journal *Annales*, which he published together with Lucien Febvre. It was in the course of this cooperative venture, and also as a result of the ensuing friendly competition between him and Febvre that Bloch developed his remarkable ability to quickly and succinctly formulate new scholarly perspectives. That is why the fight between the two coeditors was all the more painful, when, in the aftermath of the French defeat in 1940, they were forced to decide if and how the journal should continue to be published. Whereas Bloch argued in favor of discontinuing the publication of the *Annales* until the end of the War, Febvre was prepared to adapt – at least on the surface level – to the new conditions under occupation in order to continue to have a public voice. In the end, Bloch accepted this strategy and continued to publish in the *Annales* under the pseudonym 'Fougères' until the very end. At the same time, he continued to work on two book-length manuscripts, which were edited by Febvre after the War: an analysis of the French defeat (*Strange Defeat*) and a reflective work on the intellectual preconditions of historiography as: science, craft, and art (*The Historian's Craft*).

The beginning of Bloch's considerable reputation in French as well as international scholarly circles can be traced back to the 1930s. It was really after World War II, however, particularly in the closing decades of the twentieth century, that Bloch's ascendancy to the ranks of one of the world's most quoted historians took place. His books have been translated into all of the world's major languages: the number of printed copies of *The Historian's Craft* extends well into the six-figure range, one-third of which have appeared in Latin America. Bloch's heroic death has elevated him to the status of an icon, adored by intellectuals and academics representing a broad spectrum of disciplines and political convictions alike. Accordingly, one encounters a range of conflicting images of 'Marc Bloch': the Marxist or the conservative, the Jew or the nationalist, and recently even the 'postmodernist' Bloch, who supposedly drew on Nietzsche as a source of inspiration. Whereas such portrayals threaten to bury the author's historical work under ever-increasing layers of reception, recent years have seen an increased effort toward precise scholarly contextualization of this work in order to better reconstruct Bloch's contribution to the historical discipline of the twentieth century.

Abstract

Leonard Bloomfield, the most important American linguist in the first half of the twentieth century, began his studies in comparative historical philology, which he extended right from the beginning beyond the Indo-European languages by investigating Austronesian and Indian languages. While he initially adopted Wundt's notion of *Völkerpsychologie* as theoretical background of linguistics, Bloomfield developed a strictly antimentalistic, essentially behavioristic view in his groundbreaking book *Language* (1933). According to this objective approach, linguistic analysis has not to deal with what the speakers have in mind, but only with acoustic properties and principles of distribution of the basic elements of their utterances. In spite of this restrictive doctrine of '*Distributionalism*', Bloomfield relied on complex rule systems of necessarily mentalistic nature to formulate important phonological insights in a seminal paper on *Menomini Morphophonemics* (1939).

Biography

Leonard Bloomfield, one of the key figures of American linguistics, was born in Chicago on 1 April 1887. He was the son of Sigmund and Carola Bloomfield, who immigrated from Austrian Silesia, and the nephew of the renowned Indologist Maurice Bloomfield. After completing secondary school in Chicago, Bloomfield went for undergraduate studies to Harvard College in 1903, which he left with the Bachelor degree in 1906. During his graduate studies from 1906 to 1908 at the University of Wisconsin, he was impressed by Eduard Prokosch (1876–1938), a philologist at the German department, who motivated Bloomfield's decision for a career in linguistics. In 1908, he went to the University of Chicago, where he received his PhD, submitting a dissertation in Germanic historical linguistics. In March 1909, he got married to Alice Sayers.

Bloomfield began his academic career in 1909 as Instructor of German at the University of Cincinnati. He moved to the University of Illinois in 1910, where he got a position as Assistant Professor of Comparative Philology and German in 1913. He left for 1 year of graduate studies with the leading Indo-Europeanists Karl Brugmann and August Leskien at the University of Leipzig and the Sanskrit specialist Jabob Wackernagel in Göttingen. Returning to the University of Illinois in 1914, he published his textbook *An Introduction to the Study of Language*. Even though Bloomfield's primary occupation was German philology, he was convinced that the study of language must not be restricted to the historically documented Indo-European languages. He therefore began to explore Tagalog, an Austronesian language, which he described and analyzed with a native speaker of Tagalog, who was a student of the University of Illinois. Parts of this research were published in 1917. With the same motivation, Bloomfield undertook fieldwork on different Algonquian languages in 1920 and 1921, to which he returned on various later occasions. In 1921, he moved to the Ohio State University, where he was Professor of German and Linguistics until 1927. During this period, he was in close contact with the psychologist Albert Paul Weiss (1879–1931), an early advocate of behaviorism. In 1925, Leonard Bloomfield and George M. Bolling from Ohio together with Edgar H. Sturtervant from Yale initiated the foundation of the Linguistic Society of America that soon grew into the most influential organization of the field. The initial Call, drafted by Bloomfield, appeared as the opening paper of the Society's regular journal *Language*. During the summer of 1925, Bloomfield continued his Algonquian fieldwork under the auspices of the Canadian Department of Mines. In 1927, Bloomfield moved to the University of Chicago, where he held a position as Professor of Germanic Philology until 1940. His most important colleague there was the anthropologist Edward Sapir, one of the prominent students of Franz Boas. During Bloomfield's time in Chicago, the publication of his extremely influential book *Language* (1933), his growing influence on the field of linguistics in general, and his international reputation made him one of the leading representatives of American linguistics. He was President of the Linguistic Society of America in 1935, his courses at the Society's Linguistic summer institute 1938–41 were of unusual influence. Although he was not a charismatic person, easily dominating a large audience, but rather of reserved and unimposing personality, he still had an enormous impact on the field. He had few students, but many linguists regarded themselves as members of a school bearing his name. His unique effect was completely due to sober argument and the strength and clarity of his writings. In 1940, he became Sterling Professor of Linguistics at Yale University as the successor of Edward Sapir, who had moved there from Chicago 6 years before. During World War II, Bloomfield participated actively in the Intensive Language Program of the American Council of Learned Societies, applying his theoretical insights to practical problems of textbooks and courses for strategically important languages. In May 1946, he suffered a heavy stroke, from which he never fully recovered. He died in New Haven on 18 April 1949.

The Background of American Linguistics

When Bloomfield began his career, language was largely the subject matter of philological departments. Although grounded in the great tradition of European historical and comparative linguistics, which had revealed the systematic relationship among the Indo-European languages, American linguistics

gradually developed its own, independent orientation during the first decades of the twentieth century. Step by step, independent linguistic departments got established, so that a strong and influential discipline flourished, when Bloomfield left the field. Besides the philological European heritage, during this development two major factors played an important role, in both of which Bloomfield was decisively involved. First, there was a characteristic interest to document and analyze a wide variety of languages outside the Indo-European family, to which linguistic analysis was traditionally constrained. Elementary motivation for the extended perspective came from the concern for language and culture of American Indians, the systematic study of which was initiated by the great anthropologist Franz Boas (1858–1942). Among the active followers of Boas were his student Edward Sapir (1884–1939), and Leonard Bloomfield, who shared this orientation and extended it by his Tagalog studies to further language families. The interest in languages without written records raised methodological issues unfamiliar to European historical linguistics. While the neogrammarian Hermann Paul (1846–1921) in his influential book *Prinzipien der Sprachgeschichte* (1880) emphatically denied the possibility of a scientific approach to language other than the historical one, the American-Indian languages required exactly this, namely the analysis of speech independent of any written historical records. The systematic foundation of synchronic description as a scientific approach to language leads to the second characteristic trait of American linguistics, viz., the development of a specific descriptive methodology, whose characteristic, rigorous form became known as 'distributionalism'. This interest in methodological clarification of descriptive linguistics corresponds to a large extent with similar developments in European linguistics in the first decades of the twentieth century, articulated programmatically by Ferdinand de Saussure (1857–1913) in his *Cours de linguistique générale* (1916). In spite of shared intentions, American linguistics made its own specific contribution to the overall development called 'structural linguistics'. Many of the inspiring proposals, taking up Saussurean ideas in the American context, were due to Edward Sapir. But the classical formulation of the framework, which by its systematic character eventually shaped the development and spelled out its principles, was due to Leonard Bloomfield. In spite of their mutual respect and scientific appreciation, there is an interesting tension between the personality as well as the intellectual approach of these two important men. While Sapir was burning with brilliant ideas, Bloomfield organized the field by careful and systematic argument. The tension is inherent, moreover, in Bloomfield's own contribution, where interesting friction between theoretical foundation and factual insight is to be observed in several respects.

From Bloomfield's training and intense experience in Indo-European philology, two important consequences emerged for the orientation of his further research. First, a basic doctrine of the neogrammarians with whom Bloomfield had studied in Leipzig and Göttingen was the claim that sound laws have no exceptions. According to this doctrine, apparent exceptions to phonetic regularities are to be explained by additional laws, a commitment that had led to various spectacular insights. Bloomfield emphatically stressed this principle in *A note on sound change* (1928), taking it as a genuine step in his more general attempt to clarify the scientific nature of his field of interest, which had to be based on objective principles, a goal that concerned him from the very beginning. The second, equally important insight, which Bloomfield, like Sapir, adopted from comparative historical studies, was the principle of internal reconstruction that explains the differences between related dialects by means of different changes applying to common historical predecessors. This principle could be shown to apply with equal success to languages of completely different structure and history. On the basis of extensive fieldwork on Fox, Cree, Ojibwe, and Menomini, four separate Algonquian dialects, Bloomfield (1946), an important, posthumously published investigation, explained their relationship by essentially the same principles as that among the Indo-European languages, with the reconstructed dialect of Proto-Algonquian as the common historical source. This was a remarkable insight with respect to linguistic methodology as well as empirical facts. Generally speaking, the development of American linguistics, in which Bloomfield participated and which he decisively shaped, depends on European sources in various respects, but it extends and modifies this heritage in genuine and sometimes spectacular ways.

Behaviorist Orientation of Linguistics

Starting his career within the tradition of Indo-European philology, Bloomfield recognized right from the beginning the need for an overall framework, within which the study of language has its natural place and context. In his first monograph, *An Introduction to the Study of Language* (1914), he adopted Wilhelm Wundt's overall notion of 'Völkerpsychologie' to this effect. According to this conception, language belongs to the spirit or soul of its respective nation, it is, in any case, a mental entity outside the range of experimental investigation. In spite of the neogrammarians' concern for exception-less sound laws, the study of language essentially differed from the natural sciences.

A radical change in Bloomfield's attempt to provide linguistics an objective scientific foundation by general methodological standards is marked by the axiomatic approach he adopts in *A set of postulates for the science of language* (1926). In this programmatic approach, the psychological orientation of European linguistics is replaced by a strictly operationalist conception that he became familiar with through the work of his colleague Albert Paul Weiss at the Ohio State University. This perspective, systematically elaborated and convincingly illustrated in Bloomfield's most influential chef d'œvre *Language* (1933), is ambivalent or even paradoxical in characteristic ways.

On the one hand, Bloomfield criticizes Hermann Paul and other European linguists not only for their exclusively historical orientation, but even more for their imprecise psychological notions on which their linguistic concepts are based, a perspective that Bloomfield himself had accepted in his *Introduction* in 1914. He now considered the scientific analysis of language as a strictly objective matter, without any commitment to concepts taken from psychology. Under this perspective, he considered it as completely irrelevant for descriptive linguistics which sort of psychology one adheres to.

Linguistics should be established as an autonomous discipline that need not rely on any concepts other than its own.

On the other hand, Bloomfield was strictly opposed to one particular type of psychology, insisting on a rigorous exclusion of all mentalistic concepts from scientific description and explanation. He considered any resort to internal states and mental accounts of linguistic (or other types of) behavior as unwarranted at the present state of knowledge, and presumably unnecessary and hence impermissible for scientific accounts in principle. In fact, Bloomfield advocated what he called a mechanistic explanation of behavior, opting more specifically for Weiss' version of behaviorism. Both aspects of this ambivalent position – the behaviorist account of language as well as the principle of autonomous, formal analysis – are carefully worked out and applied to all kinds of concrete problems in the 28 chapters of *Language*, supporting his unusual influence during the decades to come.

Bloomfield's proposal to extend the standard behavioristic stimulus–response schema to the conditions of linguistic behavior is original, instructive, and misguided. Assuming that the relation between a conditioned response R, caused by a stimulus S, as represented in the standard schema S → R, where the arrow indicates the 'internal' causal connection between two types of activity, can be mediated by a linguistic act, Bloomfield arrives at the following proposal: An external stimulus S causes – instead of (or in addition to) the practical response R – a substitute, linguistic response r of the speaker, which now acts as a substitute, linguistic stimulus s on the hearer, causing the practical response R. Thus, the basic schema S → R is turned into the complex schema S → r…s → R, where the dotted line between r and s indicates the fact that the linguistic response r functions as the linguistic stimulus s. For the sake of illustration, Bloomfield imagines a situation, where S is the condition of being hungry and seeing an apple on a tree, while R is the act of fetching and eating it. This basic connection, S → R is now to be mediated by the substitute reaction r of making some appropriate noise, to be transcribed as, e.g., *I am hungry*, and the perception of that very noise acts as the substitute stimulus s. Thus the dotted line between r and s represents the interindividual relation connecting the production and perception of a given phonetic form, while the arrows between S and r and between s and R represent the intra-individual association of this form with the practical stimulus imposed on the speaker and the reaction produced by the hearer, respectively. What is misleading in this proposal is the fact the features of r and s, the produced and perceived signal of the utterance in question, must be identical in the relevant respects. Otherwise the assumed connection would not result. This identity cannot in general be the case for the features of S and R, as the stimulus S and the response R are supposed to be causally connected, although not, of course, to be identical. But Bloomfield explicitly considers S and R as the meaning of the utterance (s…r). In Bloomfield's example, seeing and wanting an apple and fetching do not have the same properties, and there is hardly an utterance that is causally connected to both of them. Hence even if there were a systematic, causal relation between the stimulus S and the substitute response r, this relation could not in general hold between s and R. This observation is by no means restricted to Bloomfield's original example, it rather applies to the relation between language and the conditions of use in a rather principled way. In other words, the behavioristic attempt to account for linguistic behavior in terms of conditioned stimulus–response connections was doomed to fail, even though it was taken for granted by a whole generation of American linguists and psychologists, including Skinner with his programmatic *Verbal behavior* (1957).

The paradoxical fact is that in spite of advocating this misleading theoretical orientation, Bloomfield was extremely successful not only by his impact on the field, but also in his own work on methodological issues as well as in rich descriptive and analytical work in many domains. This in turn was completely in line with his claim that linguistics should be self-contained and independent of commitments to any psychological theory. But one characteristic consequence of this theoretical orientation was the sober, albeit frustrating conviction that a systematic theory of linguistic meaning could only be developed on the basis of a complete, explicit account of all possible aspects of speaker's and hearer's environment and the physiological mechanisms determining their pertinent reactions. For this reason, Bloomfield considered the scientific treatment of semantics out of reach, at least for a period of time, and perhaps in principle, although he had no doubts about the central role of meaning for any satisfactory conception of language. For three decades, skepticism toward the possibility of a serious theory of meaning became a characteristic feature of American as opposed to European linguistics. There are explicit residues of this skepticism even in Chomsky's *Syntactic Structures* (1957), which initiated a radically different approach and paved the way toward an explicitly mentalistic theory of language.

Structural Analysis of Language

Restricting the central task of linguistics to the descriptive analysis of linguistic form indicated as (r…s), i.e., to the properties that determine the production and perception of linguistic expressions, Bloomfield developed a systematic and comprehensive account of the properties linguistic expressions might possibly exhibit. The central idea of the framework carefully laid out in *Language* is the assumption, that all relevant aspects of verbal utterances can be captured on the basis of strictly formal criteria, identifying their parts in terms of articulatory and perceptual distinctions and their subsequent classification according to their possible occurrences. More specifically, basic linguistic forms, called morphemes, are characterized as sequences of phonemes, where phonemes are classes of minimal segments identified by their articulatory properties (roughly corresponding, incidentally, to letters in alphabetic writing); morphemes can then be grouped into form classes on the basis of their distribution, i.e., observable combination, giving rise to the properties of so-called constructions that are the invariant skeleton of increasingly complex utterances.

Methodologically, this framework was based on systematic segmentation of utterances and classification of their components in terms of strictly acoustic and distributional criteria, applied to actual utterances in the sense of well defined types of physical events. In this way, segments of the

acoustic stimulus are classified as phonemes, sequences of phonemes are identified as morphemes, morphemes are grouped into several classes, particular sequences of which are classified as constructions. The details of this elegant framework – the relevant criteria for segmentation and classification, the properties of primitive and complex elements, and the specificity of the pertinent levels of structural analysis – have been intensively discussed and carefully worked out by a whole generation of linguists in the decades following the publication of Bloomfield's influential book. A rigorous and comprehensive version of the overall approach was arrived at in Harris' (1951) *Methods in Structural Linguistics*, where the canon of distributionalism is formulated in the most systematic and radical form. Bloomfield's own exposition developed the major ideas with remarkable sensitivity and respect for traditional grammatical analyses, preserving their insights where possible and correcting them where necessary, identifying their appropriate place under the new, systematic perspective. This holds for traditional notions of descriptive grammar like parts of speech, morphological categories like gender, number, tense, etc., but particularly for the important discoveries establishing the historical relationship among different Indo-European languages. In fact, more than one-third of Bloomfield's seminal book deals with topics of comparative and historical linguistics, with different types of language change, and problems of dialect geography, i.e., issues that go beyond purely descriptive analysis. Bloomfield's intimate familiarity with the history of the field, combined with his capacity to fundamentally reconstruct its aims and methodology, explains to a large extent his unique impact.

In order to accommodate the standard grammatical phenomena traditionally treated in linguistic descriptions, Bloomfield relies on the behaviorist notion of habits controlling the speaker's behavior. A habit manifests itself in a pattern of linguistic forms. Thus speakers of English have a habit according to which finite verb forms agree with their subject, as in *the boy walks* vs *the boys walk*. The paradigms of inflectional forms like *walk*, *walks*, *walked*, *walking* involved in these habits can be accounted for by systematic combinations of 'free' and 'bound' morphemes, such as *walk* and *walks*, *walked*, or *walking*. The patterns set up on this basis can then be extended to 'irregular' forms like *sing*, *sings*, *sang*, *sung*, *singing*, where the free form *sing* is combined with an alternation of the vowel instead of the affix *–ed*, yielding the form *sang*, and to even further irregularities like *go*, *goes*, *went*, *gone*, *going*, where *went* substitutes the combination *go–ed*.

In a similar way, the systematic character of habits is supposed to control the patterns of variation in the phonetic realization of linguistic forms. Thus Bloomfield argues e.g., that the masculine and feminine form of French adjectives like *plat* vs *platte*, phonetically (pla) vs (plat) 'flat', *gris* vs *grise*, phonetically (gri) vs (gri:z) 'gray', *frais* vs *fraîche*, phonetically (frɛ) vs (frɛ:š) 'fresh', and many others, are best described by taking the feminine as the fundamental form plus "the simple statement that the masculine form is derived from the feminine by means of a minus feature, namely, loss of the final consonant" (*Language*: p. 217). A second operation must then be assumed to shorten the long vowel in the resulting forms (gri:) or (frɛ:), etc., in order to account for the actual masculine (gri), (frɛ), etc. In other words, an additional vowel shortening is necessary after the previous deletion of the final consonant.

Beyond the Limits of Distributionalism

These apparently minor details of descriptive technology are worth mentioning because of the far-reaching consequences emerging from this type of analysis. The indicated description, according to which the French masculine adjective is to be construed as a regular reduction of its feminine counterpart, is certainly an elegant account of the speakers' behavior, but the assumption of an underlying form plus operations deriving its surface realization clearly stretches the notion of a habit determining linguistic behavior, because the actual behavior must now be taken to depend on preceding operations applying to underlying forms that control the articulatory patterns at best indirectly, if at all. Assuming underlying forms plus operations or rules of realization is obviously an essential step toward the recognition of internal, which means mental, representations and operations, a notion that Bloomfield rigorously wanted to exclude from scientific methodology. But he goes even further in the actually prohibited direction. In his ingenious *Menomini morphophonemics* (1939), an analysis of the sound system of an Algonquian dialect, he set up underlying forms and various operations of realization with by far more intricate conditions on their relative dependency than those required for the simple examples of French adjectives. This dependency, which Bloomfield was very much concerned with, requires an ordering of the operations up to five steps. It is obvious that internal operations of this complexity cannot be accommodated to the notion of stimulus–response habit in any serious sense. What is fascinating here, is first the depth of analytic insight in Bloomfield's analysis, and second his clear decision in case of a conflict between behaviorist methodology and descriptive adequacy. Although he was presumably not aware of the conflict, he clearly discarded the orthodoxy in favor of the insight.

In the same spirit, Bloomfield implicitly argued for an ultimately mentalistic theory of sound change, summarizing the core of his opinion by the slogan "Phonemes change" (*Language*: p. 351). This means in fact that the underlying pattern, rather than the acoustic realization, is relevant for the processes of linguistic change. In a far-sighted conclusion, based on his *Menomini morphophonemics*, he even envisaged the possibility that sound change may consist in the introduction of rules of alternation: "our basic forms do bear some resemblance to those which would be set up for a description of Proto-Algonquian, some of our statements of alternation … approximate the historical development from Proto-Algonquian to present-day Menomini" (1939). Chomsky and Halle (1968) have later developed this surprising and fascinating observation systematically in generative phonology.

Bloomfield had vividly argued for a strictly anti-mentalistic program of linguistic analysis, pointing out "Non-linguists … constantly forget that a speaker is making noise, and credit him, instead, with the possession of impalpable 'ideas'. It remains for the linguist to show, in detail, that the speaker has no 'ideas' and that the noise is sufficient" (*Language or ideas?*: p. 92). But while he complied

with this dogma by dispensing e.g., semantics from the actual linguistic research agenda, he was, surprisingly, not able to exclude mentalistic concepts from the domain of his very central concern – the analysis of linguistic form: underlying forms, derivational rules, precedence order of operations, and even phonemes as the elements that underlying forms consist of, are concepts that go beyond the mechanistic elements to be extracted from noise. This conflict between strict methodological principles on the one side and explanatory insights on the other mirrors one aspect of the above-mentioned tension between Bloomfield and Sapir, in the following sense: Although both scholars agreed on the general principles of linguistics as a scientific enterprise and also on the insights in relevant detail such as the description of Indian languages, the reconstruction of their historical relations, or the nature of sound change, Sapir always insisted on the psychological nature of linguistic facts. This is clear from his programmatic statement *Sound patterns in language* (1925), and even more so from *The psychological reality of phonemes* (1933). As a matter of fact, the orientation of Sapir's inspiring essays amounted to a mentalistic research strategy.

Thus, although Bloomfield in 1940 was Sapir's successor as Sterling Professor of Linguistics at Yale University, it was Sapir's notion of language as a psychological reality that dominated the subsequent period of post-Bloomfieldian linguistics, as shown e.g., by the title and orientation of *The Sound Pattern of Russian* (1959) by Morris Halle and *The Sound Pattern of English* (1962) by Chomsky and Halle.

But the tension persists: While Sapir (1933) and Jakobson (1941) articulated the ideas and the orientation of this development, it is still Bloomfield's radical clarification of the conceptual framework and descriptive technology that provides the indispensable foundation for practically all branches of modern linguistics. And perhaps more significantly, Bloomfield's *Menomini morphophonemics* is the paradigm case not only of a complete descriptive analysis in terms of an explicit, complex rule system, but also of an impressive victory of clear insight over methodological orthodoxy. In line with this creative tradition and conceding the amount of mentalistic machinery implied in this analysis of sound structure, strong theories of syntax and even semantics have in the meanwhile been shown to be possible and productive – in spite of Bloomfield's antimentalistic bias, but keeping to his standards and principles of linguistic analysis.

Abstract

Franz Boas was born on 8 July, 1858, in Minden, in the German province of Westphalia. He was the son of freethinkers of Jewish origin who still cherished the ideals of the democratic revolution that had taken place in Germany in 1848. Coming from such an educated bourgeois background (*Bildungsbürgertum*), he had access to books on the natural sciences and geography, and this environment had a profound impact on his future aspirations. From 1877 onwards, he studied natural sciences and geography, first in Heidelberg and then in Bonn and Kiel. After completing his PhD in physics (on the color of water) he went to Berlin, where he began to move in the academic and social circles characteristic of much of the German scientific community at that time. A major role model for him was Rudolf Virchow, the professor of medicine and anthropology.

Biography

Franz Boas was born on 8 July, 1858, in Minden, in the German province of Westphalia. He was the son of freethinkers of Jewish origin who still cherished the ideals of the democratic revolution that had taken place in Germany in 1848. Coming from such an educated bourgeois background (*Bildungsbürgertum*), he had access to books on the natural sciences and geography, and this environment had a profound impact on his future aspirations. From 1877 onwards, he studied natural sciences and geography, first in Heidelberg and then in Bonn and Kiel. After completing his PhD in physics (on the color of water) he went to Berlin, where he began to move in the academic and social circles characteristic of much of the German scientific community at that time. A major role model for him was Rudolf Virchow, the professor of medicine and anthropology.

The most decisive period for Boas was that from 1881 to 1887. In Berlin he frequented the meetings of a learned society, the *Berliner Gesellschaft für Anthropologie, Ethnologie, und Urgeschichte*, and sought to raise funds for research in North America while preparing intellectually for such a trip. In 1883–4, after a short period of service in the German army, he began to conduct field research among the Inuit of Baffin Island. This prompted him to shift his focus of interest from the landscape to its inhabitants. He found that the geographical determinism of his time did not hold up against his observations of the central Inuit, in that some of the behavior he observed was exhibited in spite and not because of the environment. After a stay in New York, he returned to Berlin to become assistant at the Museum of Ethnology in 1885. There he met a group of Bella Coola Indians who had been brought to Berlin as a living exhibit (*Völkerschau*). This encounter prompted his decision to study the American Indian peoples of the northwest coast. In 1886 he embarked on the first of his many research trips to this region, where he gained rich insights into the social organization and self-expression of the Kwakiutl. On his way back he stopped in New York, where he met the editor of *Science* magazine and was immediately appointed assistant editor. Thus, he now had the means to marry Marie Krackowitzer, a woman from New York's liberal German-speaking community, to whom he had been introduced by his uncle. He decided to remain in America, despite the fact that in 1882 he had written that 'his dearest aim' was to become a German professor. Even then, he had known that if the USA offered him 'a better chance ... I would go without hesitation.' A strong motivation for staying was that American science was, as he saw it, 'so far behind in comparison to Europe that a young man as I am, is able to accomplish much more' (Liss, 1996). There was less teaching of anthropology or ethnology than in German universities, but the strong role of the natural sciences was to impact on the development of anthropology as an academic discipline. Boas' understanding of anthropology was that of an empirical science, part of a wider trend in the social sciences, oriented towards the works of Mach, Dewey, and James (Lowie, 1956, p. 1015).

Boas' experiences in the field resulted in a rather rare intellectual approach, that of a commuter who kept travelling between different nations and their intellectual environments. He thus saw different milieus as an outsider and observer, sometimes integrated and engaged, sometimes detached. Over the course of his life he showed a strong sympathy for other such commuters. For example, he greatly encouraged George Hunt, brought up among the Kwakiutl by a Tlingit mother and a British father, to do his own fieldwork among the Kwakiutl, and also provided the funding for this work. Later, too, he was active in support of those moving between different environments, be they immigrants to the USA or people living on the fringes of their home community. Boas himself experienced the advantages of being an outside observer, maintaining that such a status sharpens one's perception of those features of a culture which are self-evident to those living within it. He was very conscious of diversity, variation, and individual differences.

Boas' basic research motivation was one for which no assumption of cultural heritage was needed: curiosity combined with ambition. For Boas, it was a particular thrill to find complex answers to simple-looking phenomena that others considered to be obvious. He stated that he was 'motivated by the effective appeal of a phenomenon that impresses us as a unit, although its elements may be irreducible to a common chance. In other words the problem that attracted me primarily was the intelligent understanding of a complex phenomenon (cf Herskovits, 1953, p. 10).

Boas assumed an entrepreneurial role in the organization of US anthropology when, in 1896, he became assistant curator of the American Museum of National History in New York (curator, 1901–5), and lecturer in physical anthropology at Columbia University (professor of anthropology, 1899–1936). Among other activities, he modernized the learned journal *The American Anthropologist* in 1898, and helped to found the American Anthropological Association in 1902. He was not only interested in founding institutions (indeed, others tried to do this as well), but in insuring their professionalization. It was this specific approach (which also brought him into conflict with those who had hoped for a broader amateur membership of the AAA), which resulted in the lasting success of his institutional activities. It should not be forgotten that the period between the Civil War and the 1920s was a great era for entrepreneurs in and around the sciences. Many institutions of higher learning, new disciplines, scientific journals, and learned societies were founded, and funding raised, but most of these efforts failed in the long run. Today, it is difficult to appreciate that Boas' efforts were unusually successful, as we only notice those institutions which have survived.

Contributions to Anthropology

Boas' major and lasting contribution lies in the methodological domain. He was always on the look out for differences and, as such, was less interested in the contemporary transformations of Kwakiutl Indian culture than in what he perceived to be its remembered past. His quest for difference also made him sensitive to variations within the ensemble of aspects which the informants or outsiders described as a culture. Any boundaries and standards were suspect to him. He raised certain issues 90 years before they were advocated by the postmodernists of the 1980s (Jacknis 1996). He was particularly skeptical about classification, and naive subjective classification aroused his anger (see for e.g., 'The principles of ethnographic classification'). A systematic discussion of the problem can be found in his linguistic paper on 'Alternating sounds'. Boas contended that people tend to classify according to familiar categories, but that anthropologists should be concerned with what was later called emic distinctions – the distinctions made by the people themselves.

Boas' empiricism shielded his work from the speculative thinking which dominated the discipline in the German-speaking countries. This methodological rigor contributed to the strong and lasting reputation acquired by American anthropology, particularly in comparison to other social and natural sciences. It was manifest in the way Boas and many of his pupils discussed and validated the results of their fieldwork. More than any other author of his time, he was conscious of two influences on anthropological sources: that of the method chosen and that of the observers' perspective, including artifacts created by the methods. He gave preference to texts emanating from the culture itself, and asked his interlocutors to produce and record texts of all kinds, not only ceremonial ones. Moreover, he carefully recorded the effects of his methods, e.g., how the phonograph was used, and how different informants influenced the style and content of dictated or written texts. The aim of this never-ending endeavor was to achieve objectivity. For Boas, a command of the native languages was essential in order to 'understand directly, what the people ... speak about, what they think, and what they do' (Boas, 1906, pp. 183–8). His concept of objectivity introduced a clear frame of reference, distinguishing his approach from that of his German and American contemporaries – a frame of reference rooted within the culture itself.

The results of Boas' fieldwork may suggest to many readers that he spent prolonged periods within the cultures under investigation, participating intensively in their everyday activities. The reality was different. His most important results were yielded by repeated short stays in the field – up to three weeks in one place. As the letters to his family show, he profited from the contrasts he experienced, seeing the surprising and the colorful in what was self-evident to the local population. The value of his reports is rooted in his insistence that each phenomenon should be viewed from different perspectives, and evidence gathered from different informants. He also integrated the latest technological methods into his approach – photography as early as 1883, and sound recording in 1887.

One of Boas' research topics was largely disregarded by the subsequent generation, namely, the place of the individual within society. Boas' interest in this subject may be seen as a legacy of the liberal German milieu in which he grew up. It was in front of the German Society of New York that he stated in 1880: 'The invention is not difficult. Difficult is the retention and further development ... . It is important to observe the fight of individuals against tribal customs. The same kind of struggle the genius has to undergo ... in his battle against dominant ideas' (cf Herskovitz, 1953, p. 75). He continued to address this question later on, in his interpretation of esoteric cults, insisting that cults should be studied in connection with the broader base of belief in society as a whole. It would be an error, he argued, to see esoteric beliefs 'as the only true form of the inner life. They might as well be considered as a reaction ... to the general cultural environment.'

The anthropological subject most intimately linked to Boas' name, and the one which prompted most references to his work in the second half of the twentieth century, was the *potlatch*. 'Potlatch' is a Chinook word for festivities, which Boas used to describe a group of redistributive ceremonies performed by the Kwakiutl. Redistribution was not the dominant feature in all cases, however. As he emphasized in his very first discussion of the subject in 1899, the creation of credit and obligation was also a central element. Moreover, the redistribution of wealth created prestige as well as obligation.

To judge from the attention he gave to the potlatch, Boas was clearly fascinated. His curiosity about otherness was captured by a phenomenon which, with historical distance, can be seen to be a travesty of one particular feature of (non-native) American civil life – too conspicuous consumption. (Both private universities and museums were dependent on such redistributions of wealth, and on the fact that benefactors were, in turn, endowed with prestige.) The Canadian administration did not recognize society's need to have ways of creating prestige. Nor did it understand that the indebtedness created by such ceremonies was, in fact, a creation of wealth and capital not entirely different from that of the modern banking system, in which the capital mobilized as credit by far outweighs the

liquid capital deposited. Boas brought these arguments into the foreground in order to defend the Kwakiutl and neighboring groups against intrusion by the Canadian administration.

Later critics observed that the potlatch, as portrayed in Boas' works, was just one momentary impression in a rapidly changing situation (Mauzé, 1986, pp. 21–63), and that Boas neglected other aspects of the economy, mainly land tenure and the livelihood of classes other than the nobility. However, these criticisms cannot diminish the importance of his discovery of a system of attributing merit which was, in itself, economically organized.

Boas was also skeptical about the evolutionism of his times, insofar as it implied a ranking of more or less progressive cultures. How was one to classify a culture which had a seemingly simple technology, but an extremely intricate social structure? For Boas, it was not acceptable to label these as 'early forms' of humanity. Assumptions about the coincidence of linguistic communities, biological inheritance, and culture were implicit in evolutionism and explicit in historical reconstructions of the 'genealogies of cultures.' Yet using material gathered from American Indians, Boas was able to show that linguistic communities, groups of descent, and culture do not necessarily coincide, and that they have in fact varied independently of each other in many cases. Thus the evolution of a given language or language group may run across different groups of descent which, over the course of time, may become members of different linguistic families.

In the first half of the twentieth century, Boas' contribution to science was most strongly identified with his work on physical anthropology. Here, he introduced the perspective of regarding differences in the human races as a phenomenon of domestication, rather than in analogy to differences in animal species. He maintained that nutrition, the instrumental and ornamental use ofthe body, crossing, and selection are the social facts shaping the variant physical appearance of humankind. Of his many empirical investigations, a study published in *The American Anthropologist* in 1912 is particularly notable. In this study, based upon a huge sample, he compared the head shapes of immigrants and their children. The shape of the head had, until then, been considered the best indicator of hereditary lines. Yet Boas was able to show that these measurements changed considerably in the children's generation. This challenged the dogma that the physical type was determined by heredity alone.

Boas did as much as he could to collect texts, especially songs, tales, and myths, and to encourage others to do the same. He maintained that such materials have the merit of bringing out 'those points which are of interest to the people themselves' (Boas 1916, p. 393). He objected to other authors classifying genres according to their subjective standpoint or the standpoint prevalent in their own culture, and referred instead to the categories used by the people themselves (emic categories) – a procedure which, even today, is not always followed. He rejected explanations of symbolism which were not based on explicit data from the culture itself as pure speculation, whether they be such as those of the German *Kulturhistorische Schule*, or Freudian. In contrast, he placed particular weight on the recognition of myths and tales as artistic creations, arguing that these should not only be a source of anthropological research, but valued as a product of human creativity.

Boas' attitude to politics was interested but rather detached. The liberal German milieu in which he grew up advocated the separation of science from religion and politics. The sociologist Max Weber, who later matured in the same milieu, formulated the idea of value freedom in science. Having experienced the repression of such scientific freedom by the institutions of power and religion in the nineteenth century, the liberal scientific community saw this conception of science as an important basis for the growth of scientific endeavor and discourse – a neutral medium for the way society saw itself and for societal development. Detachment did not mean indifference, however. Boas had already described the goal of science to be 'the ice-cold flame of the passion for seeking the truth.' Moreover, observations of prejudice called for scientists to speak out. On several occasions, Boas spoke out against racial prejudice, defending the American 'Negro,' underlining the evidence of high cultural achievement in the African past, criticizing the US and Canadian policies which discriminated against Indian customs (namely the potlatch), censuring war and, last but not least, condemning anti-Semitism. His texts against anti-Semitism were printed in a widely read German newspaper (*Frankfurter Zeitung*) in 1926 and later distributed as leaflets by the German anti-Nazi resistance.

Influences

Boas' legacy cannot be identified with a particular theory. In contrast to other authors, after his investigation of the Inuit he produced few texts which attempted to provide a general ethnography. The organization of findings in his texts often obscures information rather than elucidating it. Central theoretical arguments are typically found neither in the introduction nor in the summary, but somewhere in the middle of the text, sometimes as footnotes. He did, however, introduce some important methodological approaches. It was Boas who cross-bred physical anthropology with ambitious statistical methods. He and his pupils were the first to take linguistic approaches, looking for the categories by which language was organized in the mind. This later lead to the study of phonemics with his pupil Edward Sapir, and later still, to the idea of the categorial grammar which takes Boas' perceptive of trying to find by induction categories immanent to the language itself, rather than transplanting the categories of Indo-German grammars.

In the decade after his death, more was written about Boas than about any American anthropologist before him. This may have created the impression of a Boas School. Indeed, his pupils included such anthropologists as Ruth Benedict, Melville Herskovits, Robert Lowey, Margaret Mead, Ashley Montague, and Edward Sapir. Later, however, harsh criticisms such as those of Lesley White exposed some limitations in Boas' work. His didactical methods apparently did not meet the standards of the North American universities. Moreover, considering that those who studied under him represented 'the greatest variety of interests, methods and theoretical orientation,' one cannot but agree with Herskovits' early statement (1953, p. 23) that 'the term "Boas' school" ... is a misnomer.'

However, one cannot overlook the fact that functionalism and its later variations such as conflict theory owe their success to the methodological rigor introduced in Boas' aversion to speculative anthropology, and to the institutional foundations he laid. Evidently, Boas and Malinowski – the leading Anglo-Saxon anthropologist of the time – tended to ignore each other, although both were trained in the German approach to the natural sciences. In the few remarks he made on Malinowski and functionalism, Boas named the close observation of daily life as a merit, though underlining that fieldwork was already an established practice in US anthropology before the beginning of the twentieth century. He criticized the explanation of human behavior on the basis of the actual social environment alone, the approach taken in earlier British functionalism. Boas felt reference to historical data to be indispensable for an understanding of ongoing processes (cf Boas 1938).

It was thanks to Boas that exotic presentations of unexplainable behavior and the reduction of unfamiliar cultural forms to an irreducible genetical heritage were gradually excluded as forms of scientific explanation. He brought the assumption of rationality to the foreground, making this the starting point of anthropological explanation. This does not imply that all human behavior is rational, or that all social institutions are functional (in fact, Boas abhorred such generalizations). However, it does mean that explanations of individual behavior and culturally encoded behavior should relate to the goals, cultural strategies, and environmental conditions of the informants. Of course, behavior may still fail to achieve its goals or may even be erratic in view of all possible goals.

The 1980s and 1990s saw a return to the skepticism which distinguished Boas' approaches from those of most earlier theorists. His legacy is an antidote to reification (*Verdinglichung*), reminding us that any culture is multifaceted and continuously changing, and that individuals may row against its currents.

Abstract

Norberto Bobbio was the leading Italian legal and political philosopher of the second half of the twentieth century. His life and work were conditioned by the vicissitudes of Italian democracy both before and after the Second World War. The experience of Fascism, the ideological divisions of the Cold War, and the transformation of Italian society during the 1960s and the 1970s, which he described so evocatively in his *Ideological Profile Of Italy in the Twentieth Century* (1969a, 1995a), prompted and enriched his passionate defense of the constitutional 'rules of the game' against those who denied their relevance or would overturn them for reasons of pragmatic convenience.

Biography

Norberto Bobbio was born in 1909 into an affluent, professional, upper-middleclass Turin family. He attended the local university, where he took degrees in both Jurisprudence and Philosophy. His main influence was as a legal and political philosopher. He brought to both a keen civic as well as intellectual engagement, while never sacrificing academic rigor or independence. His academic significance in both fields lay in combining conceptual analysis with a positivist orientation that focused attention on the institutional sources and embodiment of law, on the one hand, and the social and procedural preconditions of democratic politics, on the other. As a public intellectual, he was a lifelong proponent of social democracy. He played a key role in seeking to move the Italian Communist Party (PCI) toward a principled rather than purely pragmatic acceptance of the norms and forms of liberal democracy and in the promotion of a centre Left capable of taking on the centre Right coalition that ruled Italy for much of the postwar period. He was also a prominent campaigner for nuclear disarmament and a pioneer in the field of international political thought.

Bobbio taught jurisprudence first at the University of Camerino and then at Sienna and was appointed to a Chair at Padua in 1940. In 1948, he replaced his teacher Gioele Solari as Professor of Legal Philosophy in Turin, a post he held until 1972. He then took the chair in the newly created Faculty of Political Science in Turin, where he remained until the then statutory age of retirement of 75 in 1984. He was a member of the Accademia dei Lincei, a Corresponding Fellow of the British Academy from 1966, and longtime editor (together with the philosopher Nicola Abbagnano) of the *Rivista di Filosofia*. Bobbio received, among other awards and honors, the Balzan Prize in 1994 (for Law and Political Science: government and democracy) and diplomas *honoris causa* from the Universities of Paris (Nanterre), Madrid (Complutense), Bologna, Chambéry, Madrid (Carlos III), Sassari, Camerino, Madrid (Autónoma), and Buenos Aires.

Bobbio played an important intellectual role within Italian political life and commentated regularly on Italian politics for the Turin daily *La Stampa*. In 1942, he joined the then illegal radical liberal party, the Partito d'Azione ('Party of Action'), and was briefly imprisoned in 1943 and 1944. He ran unsuccessfully in the elections for the Constituent Assembly of Italy in 1946. Throughout the 1950s, the 1960s, and the 1970s, he was a powerful advocate of liberal democratic values against both the Marxists in the PCI and the New Left and extremist groups outside it, while also condemning the corrupt electoral practices of successive governments to exclude the first and their often illiberal measures to tackle the second. The year of his retirement, Bobbio was nominated by President Sandro Pertini to one of the five life senatorships, and sat in the upper house as an independent socialist. In 1992, he came close to being elected President as a compromise candidate. However, he confessed to finding decision making difficult – his talent was always for spotting problems rather than solutions – and he was relieved the bid failed. He died as he had lived his life, with great dignity – instructing his doctors not to intervene when taken into hospital just after Christmas 2003. He died on 9 January 2004, his status marked by the Italian President's immediate departure for Turin to be among the first mourners.

Major Works and Publications

Bobbio grew up in Turin in a well-off bourgeois family. He has characterized his parents' sympathies as 'filo-fascist,' regarding Fascism as a necessary evil to guard against the supposedly greater danger posed by Bolshevism – a threat that seemed all too present following the occupation of the Turin Fiat works in 1921–22 by the *Ordine Nuovo* group gathered around the Marxist theorist and future leader of the Communist Party of Italy, Antonio Gramsci (Bobbio, 2002: pp. 15–16). At school and university, however, he became acquainted with many of the leading lights of the largely antifascist Turin intelligentsia. These included the novelists Cesare Pavese and Carlo Levi, his future publisher Giulio Einaudi, the critic Leone Ginsburg, and the radical politician Vittorio Foa – the last two being particularly close friends at the time.

Bobbio never met the two best-known martyrs of Turin's antifascist movement – Gramsci and the 'revolutionary liberal' Piero Gobetti, though he became Director of the center dedicated to the latter's memory and his own papers have now been housed there along with Gobetti's. However, some of his

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61164-9

teachers and friends had been involved with them and contributed to their journals (Bobbio, 2002: pp. 17–21). Despite associating with certain key opponents of the regime, a number of whom were imprisoned, he largely kept his head down. Indeed, there was something of a furor when in 1992 the Italian weekly *Panorama* published a somewhat groveling letter he had written to Mussolini in 1935. Earlier that year Bobbio had been arrested and detained for 7 days on suspicion of antifascist activities and sympathies. The resulting record had led to his exclusion from the promotion process for a permanent professorship. The letter gave examples of his devotion to the Fascist cause in an attempt to get a police caution removed – something later achieved when a family friend within the Fascist hierarchy also intervened on his behalf. Bobbio confessed that the letter had brought him face to face "with another self who I thought I had defeated forever" (Bobbio, 2002: p. 31). His defenders, though, among them the surviving friends he had apparently disavowed, pointed out that the letter had been written at the height of Fascism's power simply to keep his job. It had revealed not only that Bobbio clearly was not considered a dutiful Fascist but also the debasement the authorities imposed on all their subjects.

In his autobiography (1997), Bobbio described this first half of his life as belonging to his prehistory. Yet one can see Bobbio's own deep commitment to democracy and the rule of law as flowing from this humiliating experience. Far from detracting from his opposition to authoritarianism in all its forms, the incident – that encapsulates life under a dictatorship – makes it all the more comprehensible and profound. The fall of Mussolini on 8 September 1943 catapulted him along with so many others of his generation from a state of total exclusion from political life into active involvement with it. Bobbio had been close to the 'liberal socialist' circle of intellectuals since the late 1930s. This group became part of the Party of Action, the main noncommunist resistance movement. Bobbio played a minor role, but did engage in some clandestine activity against the German occupation and was briefly imprisoned from 1943 to 1944. Although intellectually influential, the *azionisti* lacked a popular base. A candidate in the 1946 elections for the Constituent Assembly, he was not elected and returned to academic life. However, the party's slogan 'Justice and Liberty' captures the central theme of much of Bobbio's subsequent work – how to unite the liberties beloved of liberals with the socialist demand for social and economic justice. It was his commitment to these twin ideals that was to give him such an influential place within Italian political life, rendering him the perfect critical interlocutor between the Communist Party, on the one hand, and the various governmental parties gathered around the Christian Democrats, on the other.

Bobbio's first book, *The Phenomenological Turn in Social and Legal Philosophy* of 1934, was followed in 1938 by a monograph on *The Use of Analogy in Legal Logic* and in 1944 by a critical study of existentialism, *The Philosophy of Decadence* – the first of his books to be translated into English (Bobbio, 1948a). Over this period, Bobbio gradually dissociated himself from the broadly idealist approach to philosophy then dominant in Italian universities. He was friendly with the philosopher of science, Ludovico Geymonat – also based at Turin – and together with him helped establish the interdisciplinary Centre for Methodological Studies. Bobbio now set himself the task of elaborating a general theory of the practice and validity of law, breaking with the attempts of most contemporary Italian philosophers to offer a speculative philosophy of the idea and morality of law. In elaborating his version of legal positivism, he drew on the writings of Hans Kelsen, whose work he had come across as early as 1932. This research ultimately bore fruit in a number of books based on his Turin lectures, of which the most important are *A Theory of Judicial Norms* (1958) and *A Theory of the Legal Order* (1960) – both still in print – and studies of Locke, Kant, and legal positivism. Between 1955 and 1970, he also published three collections of his most important essays. These writings had a similar place in Italian academic legal circles as the work of H.L.A. Hart in British universities, and both men held each other in high esteem.

Bobbio's legal studies fed into his political writings. Influenced again by Kelsen, he adopted a procedural view of democracy as consisting of certain minimal 'rules of the game,' such as regular elections, free competition between parties, equal votes, and majority rule. His theory of politics was additionally enriched by a strong realist current deriving partly from Hobbes, and partly from his studies of the Italian pioneers of political science, such as Gaetano Mosca and Vilfredo Pareto (collected as 1969b, 1972), whose reputation Bobbio did much to resurrect. Bobbio had produced the first Italian edition of Hobbes' *De Cive* (1948b), earning the plaudits of the German scholar Carl Schmitt, who he had briefly met in Berlin in 1937. Bobbio later dedicated numerous studies to the English philosopher, a collection of which were published in 1989 and appeared in English a couple of years later (Bobbio, 1989b, 1993a). He drew on Hobbes to modify what he now saw as unsatisfactory elements of his earlier Kelsenism. Bobbio regarded Kelsen as caught uncomfortably between a purely formal account of law, on the one hand, and a substantive position grounded in what he called the 'basic norm' underlying all law, on the other. The missing dimension was the institutional context of law making and its relationship to the exercise of power. Unlike earlier legal positivists, such as John Austin, Bobbio did not thereby equate law with the commands of the sovereign. His point was rather that law and rights were best conceived as a historical achievement belonging to a particular form of constitutional and democratic state.

Bobbio's shift from a pure theory of law to a concern with its political embodiment was marked by his moving to the newly created chair in Politics at Turin in 1972. The essays from this period were later collected as *The Future of Democracy: A Defense of the Rules of the Game* (1984a, 1987a), perhaps the most original of his books; *State, Government and Society* (1985, and published in English as *Democracy and Dictatorship* 1989d); and *The Age of Rights* (1990, 1996a). Bobbio's linking of the rule of law and rights to the distribution of power produced by liberal democracy informs his contributions to the political debates of the period. His prime concerns from the 1950s onward were to enter into dialogue with the Communist Party and build a social democratic opposition in Italy. Indeed, the latter could only be achieved if the Communists, the largest grouping on the left in Italy, could be weaned away from the Soviet Union and converted to liberalism. It is no accident that he published the first (and for

some years the only) Italian study of Karl Popper's *The Open Society and its Enemies* as early as 1946, in a journal appropriately entitled *Il Ponte* (The Bridge). Bobbio was a founding member of the European Society of Culture, which had this critical dialogue as a goal. His first book of political essays, *Politics and Culture* (1955), consisted largely of a debate with the Marxist philosopher Galvano Della Volpe over whether socialist legality could be based on anything other than traditional liberal rights – a discussion that ultimately prompted the intervention of Palmiro Togliatti, the leader of the PCI.

This theme resurfaced in Bobbio's next major foray into politics in the 1970s. The spur this time came from the 'historic compromise' between the PCI and the Christian Democrats, whereby the PCI, which had a strong foothold in local government and was the main opposition party, was given access to positions in the state while being denied participation in central government. PCI leaders were worried that terrorist violence, some of it certainly promoted by the security services, might be used as an excuse for a right-wing coup should they appear to be too strong – a fear reinforced by the fate of Allende in Chile. They sought to make themselves nonthreatening to the status quo, therefore, while strengthening their position within the Italian political system – a tactic they associated with Gramsci. Bobbio's interventions were to challenge the coherence of this Euro-communist strategy of a 'third' way between liberalism and Soviet communism. In a series of essays, he criticized Marxism for lacking a theory of the state or democracy, and implicitly urged the PCI to become a social democratic party. These essays were published as *Which Socialism?* in 1976 with an English edition in 1987b. It should be emphasized, however, that Bobbio was as harsh a critic of the corruption of Italian politics and of the role of the noncommunist Socialist Party under Bettino Craxi in upholding that system and taking it to new depths. It was entirely in keeping with his stance that his first article following the collapse of the former Soviet bloc should not be a piece of liberal triumphalism but a reminder that the cause of social justice that had inspired communism remained as pressing as ever, and that liberals could not afford to ignore it (1989e,f). He later reiterated this thesis in his long essay *Left and Right* (1995b, with an English edition published as 1996b), which entered the Italian bestseller lists, in which he argued that the search for a reconciliation between the claims of liberty and equality still provided the key issue of modern politics and the main dividing line between political parties.

The other political issue associated with Bobbio was the peace movement. This too bears a direct relation to his academic work. His view of the political character of law led him to recognize the need for a political theory of international relations. In a series of pathbreaking essays, he explored the possibility for global forms of democracy to give meaning to international law. He was a passionate critic of nuclear weapons, which he saw as making war intrinsically unjust, and a member of the Bertrand Russell Foundation. His writings on this issue were collected in the volumes *The Problem of War and the Roads to Peace* (1979) and *The Absent Third* (1989a). He was not a pacifist, though many of his supporters were surprised when he supported the Gulf War – a position he defended in his book *A Just War?* (1991).

An esteemed political commentator, who wrote regularly for the Turin-based daily *La Stampa*, he kept aloof from a direct involvement in party politics and refused invitations to stand as a senator. He had a healthy disdain for academic politics and, apart from a stint as Dean from 1973 to 1976, kept clear from positions of power and deplored the way so many Italian professors built up extensive patronage networks to secure posts for their pupils. He took his teaching duties extremely seriously, and sympathized with that element of the 1960s' student movement (of which his eldest son was one of the leaders) that complained about the large numbers of Italian academics who engaged in extracurricular activities to the detriment of their university responsibilities. Unbelievably prolific, many of his books had their origins in his lectures and he put on new courses for almost every session. He was deeply disappointed by the failure of the centre Left to establish its hold on Italian politics and became an outspoken critic of Berlusconi, lamenting in a book-length interview on *The Idea of the Republic* (Bobbio and Viroli, 2001, 2003), how the second republic appeared to lack any of the idealism of the first. Significantly, in a series of essays *In Praise of Meekness* (1994, 2000), he turned his attentions to the nonpolitical virtues and the issue of how to respond to evil in a corrupt world. His last works included a subtle study of the meaning of old age in contemporary societies, *De senectute* (1996c, 2001).

The Paradoxes and Broken Promises of Democracy

As the foregoing discussion shows, Bobbio was a prolific author who wrote on a wide range of topics in legal and political philosophy. He was not a systematic thinker, tending to react to the views of others and the events of the day. His forte was to ask pertinent questions rather than offering answers. Nevertheless, a core concern runs through his writings: namely, the desire to link liberalism, socialism, and democracy and to show how each entailed the other. He firmly believed that there could be no democracy without both liberal rights and social justice, yet he also contended that these were grounded in their turn in a democratic division of power in which citizens were treated as political equals. In common with the Italian political tradition more generally (Bellamy, 2014), his idealism was grounded in and constrained, and occasionally subverted, by realist considerations concerning the nature and limits of politics. For example, he saw rights as a historic and political achievement rather than as universal principles that lie outside or provide the preconditions for politics.

As a result, tensions always exist in Bobbio's thought between the various ideals he espouses and their realization, with the mutually entailing notions of liberalism, socialism, and democracy being each presupposed by while at the same time in potential conflict with the others. A good example of this feature of Bobbio's thinking in his famous account of the 'paradoxes' and 'broken promises' of democracy. Bobbio advocates a minimal definition of democracy that consists of the following basic 'rules of the game':

1. That all citizens who have reached the age of majority, regardless of sex, race, creed, or economic condition, possess political rights and can vote on collective issues or elect someone to do so for them.

2. That everyone's vote has equal weight, counting for only one.
3. That all citizens can vote according to their own freely-arrived-at opinion, that is in a free competition between rival political groups, which vie with each other to aggregate demands and transform them into collective decisions.
4. That they have a free choice in the sense of having real alternatives to pick from.
5. That they are bound by the majority decision (whether relative, absolute, or qualified).
6. That no majority decision can limit the rights of the minority to become in their turn, and on an equal basis, the majority (Bobbio, 1987b: p. 66).

Bobbio gives three reasons for preferring democratic government to other forms. The first, ethical defense, derives from Rousseau's formula that liberty consists in obeying laws that we have prescribed to ourselves – a condition most nearly approximated by democracy. The second, political justification, regards it as the best available protection against the abuse of power, since it shares sovereignty among the people as a whole. Finally, from a utilitarian standpoint, democracy is preferable to autocracy on the grounds that the people are the best interpreters of their own collective interests. This point, as Bobbio notes, is the most debatable, since the collective interest is not identical with the sum of individual interests. However, provided one assumes that everyone has agreed to cooperate to find a mutually beneficial solution, and that each person has a better-than-even chance of being right, then (as Condorcet proved) the majority will be more often right than a single voter (Barry, 1967: pp. 112–126).

The above arguments have a distinctly Rousseauvean tenor, and hence might seem to provide a prima facie case for preferring 'direct' forms of democracy to 'indirect' or representative models. For the latter, as practiced in most Western countries, reduces the autonomy and sovereignty of the people by delegating large areas of decision making and encourages self-interested voting for different factional groups, rather than a disinterested adjudication on the common good. Indeed, Rousseau himself gave the most comprehensive account of why democracy as he understood it could not work without modification within modern societies:

> How many conditions that are difficult to unite does [a democratic republic] pre-suppose! First, a very small state, where the people can readily be got together and where each citizen can with ease know all the rest: second, great simplicity of manners, to prevent business from multiplying and raising thorny problems [which empowers those 'in a position to expedite affairs']; next, a larger measure of equality in rank and fortune, without which equality of rights and authority cannot long subsist; last, little or no luxury – for luxury either comes of riches or makes them necessary; it corrupts at once rich and poor, the rich by possession and the poor by covetousness; it sells the country to softness and vanity, and takes away from the state all its citizens, to make them slaves one to another, and one and all to public opinion.
>
> Rousseau, 1973: p. 217

For Bobbio these discrepancies are indicative of the four main 'paradoxes of democracy' facing us today. The first paradox arises from the need for ever more democracy in conditions that are increasingly inimical to its functioning. The 'iron law of oligarchy' operates the larger the state becomes, so that direct democracy degenerates into the rubber-stamping of executive decisions. The second paradox derives from the growth not only in the size of the state but also of its functions. This process leads to the development of bureaucratic structures in which power is organized hierarchically, descending from above, rather than democratically, ascending from below. Even worse, this phenomenon increases in step with the expansion of democracy itself, since the latter produces ever greater demands on the state, which in turn requires ever newer mechanisms to satisfy them. The third paradox refers to the effects of technology on industrial societies, which means more and more decisions call for specialized knowledge to solve them, so that democracy is subverted by technocracy (quite the reverse of what Marx and Lenin supposed). The final paradox belongs to the contradiction between democracy and mass society. Although mass involvement potentially means more democracy, the pressures toward social conformity produced by the former undermine the sense of individual responsibility presupposed by the latter. For example, the growth of information technology potentially gives greater access to the workings of government and could facilitate a more active and informed participation of citizens in making decisions previously left to politicians or administrators. However, it has also given the state, through the storage of private files and the use of the media, more persuasive and subtle ways of manipulating arid spying on us (Bobbio, 1987a,b: p. 72, pp. 96–97).

All the above paradoxes reflect the double-edged nature of the processes at work in contemporary society. Summarizing these effects, Bobbio remarks how 'state' and 'civil society' have become increasingly intertwined. While the state has been 'socialized' through the influence of greater democratic control, democracy in turn has induced increasing intervention by the state in society:

> These two processes are represented by the two aspects of citizenship, that of the citizen qua participant and that of the citizen qua state protected subject, which often conflict with each other within the same person. For through participation the active citizen calls for greater protection from the state and thereby reinforces the very state which he or she wishes to control.
>
> Bobbio 1985: pp. 41–42.

State and society are thus two separate but interdependent moments of the modern social and political system. 'Direct' democracy, in so far as it aspires to absorb state functions within society through schemes for self-administration through collective decision making, falls victim to the dialectic of modern politics. Only representative democracy, albeit in modified form, can meet this challenge. Yet a representative system will always fall short of the radical expectations of democracy and is itself subject to all four paradoxes: being an elite and, via its association with parties, a bureaucratic system that is often itself overly dependent on technocrats in the state administration and business, and both an exploiter of and often at the mercy of the mass media. As such, democracy is destined to always 'break its promises.' It

provides an ideal to which one is moved to aspire, but in reality always disappoints. Real democratic systems will always fail to deliver on the democratic ideal. Indeed, he came to regard Silvio Berlusconi and Italian democracy post 1989 more generally as epitomizing these paradoxes and broken promises of real democratic systems.

Conclusion

Norberto Bobbio was the model of the engaged intellectual. He was deeply involved in the politics and culture of his time yet saw his role as much as an analyst as an advocate. Bobbio's thought has been criticized as mired in contradictions, not least due to his attempt to reconcile liberalism and socialism (e.g., Anderson, 1988). Yet in many respects, his awareness of these tensions was a source of his distinctiveness and strength as a political theorist. He never looked for easy solutions or sought to sacrifice principle for a pragmatic advantage. Rather, he insisted that we should strive to uphold certain basic ideals, while being ever aware of the difficulties standing in the way of their realization. He believed the good should not be sacrificed either for the sake of an elusive and unreachable best or for something worse than is achievable. His absence from contemporary debates is a major loss not only to political thought but also to Italian politics, where he served as his country's political conscience.

Body: Anthropological Aspects

Thomas J Csordas, University of California, San Diego, CA, USA

Abstract

The theoretical status of 'the body' in cultural anthropology has evolved in roughly four stages: (1) in earlier decades of the twentieth century, it was an implicit, taken-for-granted background feature of social life; (2) beginning in the 1970s, the body became an explicit topic of ethnographic concern; (3) from the 1980s, the body began to become a problem to be accounted for with respect to its cultural and historical mutability; and (4) by the century's end, the body offered a theoretical locus for rethinking various aspects of culture and self. This conception of the changing status of the body in anthropology guides the exposition that follows.

Early Reflections on the Body

Although the body was traditionally implicit in anthropological writing, a rereading of older sources is nevertheless likely to offer a surprising richness of insights on bodiliness. Paul Radin, for example, explicitly discusses indigenous philosophy of the body in a chapter on 'The Ego and Human Personality' (1927). In what we would today call an attempt to formulate an ethnopsychology of the person, he emphasized the Maori distinction between material (substance) and immaterial (form) aspects of the body as the resting place of various components of the person. In its anatomical aspect, the Maori body was associated with psychical rather than physiological functions. After going on to discuss the person among the Oglala Dakota and the Batak, he concludes that these ethnotheories display an 'inability to express the psychical in terms of the body,' but must project it onto the external world (1927: pp. 273–274). Robert Lowie, in a chapter on 'Individual Variability' in religious experience, dealt with issues relevant to embodiment under the heading of 'sensory types' (1924: pp. 224–231). His data for this discussion were instances of visionary, or revelatory imagery. Noting the absence of studies in this area by anthropologists, he was concerned with the manner, in which imagination is concretely engaged with the various sensory modalities. Drawing primarily on Crow material supplemented by evidence from other North American tribes and from the African Bushmen, he suggested that the cross-cultural data conformed with the then-current psychological findings that visual imagery predominates in frequency over imagery in other sensory modalities, though certain individuals might show a propensity toward auditory or even motor, tactile, and kinesthetic imagery. Maurice Leenhardt (1947/1979) reports a conversation between himself and an elderly New Caledonian philosopher about the impact of European civilization on the indigenous cosmocentric world. His interlocutor said that "What you've brought us is the body." For Leenhardt, this pronouncement upends a stereotype that presumes the body lies on the side of nature (the primitive) and spirit on the side of culture (the civilized). Leenhardt vividly suggests that the very possibility of individuation has as its condition of possibility, a particular mode of inhabiting the world as a bodily being.

Some of the earliest sustained treatments of the body in its cultural and social dimensions were Robert Hertz's ([1909] 1960) study of the symbolic preeminence of the right hand and Marcel Mauss' ([1934]1950) justly famous article on techniques of the body. Mauss' work is almost universally cited as a precursor of the contemporary interest in the body. It anticipates the notions of practice and habitus later elaborated by Pierre Bourdieu (1977), though the notion of habitus had already passingly been used with a similar sense by Max Weber in his discussion on religions of ethical salvation. Important historically is the relation between this article on the body and Mauss' fragmentary but influential discussion of the person, appearing only 4 years later (1938/1950). In the latter article, he suggested that all humans have a sense of spiritual and corporal individuality, and saw the person as associated with the distinction between the world of thought and the material world as promulgated by Descartes and Spinoza.

Anthropology of the Body

In later decades, attention to the body largely took the form of studies of gesture, nonverbal communication, kinesics, and proxemics (Benthall and Polhemus, 1975). In these studies, interest in the body in its own right was subordinated to interest in communication as a cultural process, with the body serving as the means or medium of communication. In other words, rather than beginning with a concern for bodiliness per se, these analyses took language as their model, using a linguistic analogy to study various types of languages of the body. Perhaps for this reason, they are rarely cited in the literature on the body, and embodiment that has appeared in abundance since the late 1980s.

Two books by Mary Douglas define the threshold of a true anthropology of the body. In 'Purity and Danger' (1966), she made her famous argument that the dietary rules in the biblical book of Leviticus summarized the categories of Israelite culture, and made the general claim that social system controls induce consonance between social and physiological levels of experience. In 'Natural Symbols' (1973), Douglas made her equally famous argument that the bodily state of trance in different societies corresponds to the state of social organization characterized in terms of the 'grid' of cultural classifications and the 'group' control over the ego as an individual actor. Building on Mauss, she rejected both Edward

Hall's work on nonverbal communication and Claude Levi-Strauss' work on mythical thought, on the grounds that they lacked hypotheses to account for variation across cultures. In presenting such a hypothesis, she committed herself to understanding the body as a 'medium of expression,' arguing that a drive to achieve consonance across the levels of experience requires the use of the body to be 'coordinated with other media' so as to produce distinct bodily styles, and that 'the physical body can have universal meaning only as a system which responds to the social system, expressing it as a system' (1973: p. 112). Overall, Douglas' legacy to the anthropology of the body is encapsulated in her conception of 'two bodies,' the physical and social, 'the self and society' (1973: p. 112).

Blacking's (1977) introduction to his edited volume on anthropology of the body offers a programmatic outline that is both more concerned with the body per se and its contribution to social processes than with the manner, in which it reflects or expresses those processes, and which is more explicitly concerned with the relation between the biological and cultural. Its 'chief concern is with the cultural processes and products that are externalizations and extensions of the body in varying contexts of social interaction,' and it rejects the distinction between the biological and cultural anthropology on the grounds that culture has shaped the physical body, while features of culture such as language are biologically based (1977: p. 2). Blacking sketches four premises for the anthropology of the body: that society is a biological phenomenon, all humans possess a common repertoire of somatic states, nonverbal communication is fundamental, and the mind cannot be separated from the body (1977: p. 18). Blacking emphasized the liberatory potential in anthropology of the body insofar as it could contribute to dealienation and 'ownership of our senses.'

Once the body emerged from theoretical anonymity to become a recognized topic in its own right, its omnipresence in social life led to a multiplication of ways to organize its study. Following Douglas' inspiration to recognize 'two bodies,' Nancy Scheper-Hughes and Margaret Lock (1987) suggest that they instead consider 'three bodies,' including the individual body, social body, and body politic. John O'Neill (1985) suggested thinking in terms of 'five bodies,' including the world's body (i.e., the anthropomorphized cosmos), the social body, body politic, consumer body, and medical body.

The Body as a Theoretical Problem

It was not long between the emergence of the body as a topic and the transformation of the body into a problem. This aspect of the body's career in anthropology is deeply bound up with the career of anthropology in interdisciplinary studies. Scholars from virtually every branch of the human sciences have been influenced by reformulations of basic understandings of the body through the work of Michel Foucault on the discursive formations that have constituted the hospital (1973), the prison (1977), and sexuality (1978); the work of Pierre Bourdieu (1977) on practice and habitus; and the work of Maurice Merleau-Ponty (1962) on perception and embodiment. Equally, scholarly understandings of the body have been transformed by feminist works including Luce Irigaray's (1985) extended critique of psychoanalysis and Donna Haraway's (1991) studies of the encounter between gendered bodies and technology. Although it is a simplification to formularize the scope and nature of the theoretical sea change effected through such works, two aspects stand out. First, though work such as Blacking's called into question the distinction between mind and body, and between biological and cultural anthropology, subsequent work has gone even farther in calling into question the degree, to which biological nature can be considered a stable substrate of human existence. Second, though Douglas encouraged us to think in terms of two bodies corresponding to self and society, subsequent work has gone beyond her tendency to treat the body-self as a passive lump of clay or tabula rasa, upon which society imposes its codes, toward understanding it as a source of agency and intentionality, taking up, and inhabiting the world through processes of intersubjective engagement. This radical shift has made the body a central problem, and one of some urgency, across a range of disciplines. Thus, Emily Martin, whose own work on gender, science, and technology (1987, 1994) has contributed significantly to the body's move to center stage in social theory, has posed the question of the 'end of the body' as we have known it.

In addition, there has been a chorus of statements about the historical malleability of the body. The radical 'situatedness' of the body extends even to the domain of biology itself, as is evident in recent feminist theory that eliminates 'passivity' as an intrinsic characteristic of the female body, and reworks the distinction between sex and gender (Haraway, 1991: pp. 197–198), as well as the decoupling of female sexual pleasure with the act of conception. With biology no longer a monolithic objectivity, the body is transformed from object to agent (Haraway, 1991: pp. 197–198).

The contemporary cultural transformation of the body can be conceived not only in terms of revising biological essentialism and collapsing conceptual dualities, but also in discerning an ambiguity in the boundaries of corporeality itself. Some have suggested that in contemporary civilization, the human body can no longer be considered a bounded entity due to the destabilizing impact of social processes of commodification, fragmentation, and the semiotic barrage of images of body parts. Others have explicitly problematized bodily boundaries between animal and human, animal/human and machine, and human and divine. Exploring these cultural boundaries can be incredibly rewarding and remarkably problematic given the circumstances of corporeal flux and bodily transformation sketched above.

Embodiment and Culture

This radical rethinking has also created an opportunity for a rethinking of culture and self from the standpoint of the body and embodiment. If the body was often a background feature in traditional ethnographies, so it has often remained implicit in anthropological theories of culture, which historically have been cast in terms such as symbols, meanings, knowledge, practices, customs, or traits. The problematizing of the body and its movement to the center stage in social theory has also led to the emergence of studies that do not claim to be about the body per se, but instead suggest that culture and self can

be understood from the standpoint of embodiment as an existential condition, in which the body is the subjective source or intersubjective ground of experience.

This development can be seen taking place concretely over time in the work of a variety of anthropologists. For example, in the early 1970s, Strathern and Strathern produced a conventional monograph on body decoration in Mount Hagen, New Guinea. More recently, each author has developed their thought in light of a reformulated understanding of embodiment (A. Strathern, 1996) and its gendered nature (M. Strathern, 1992). Terence Turner (1995) published an influential essay on body decoration among the Brazilian Kayapo, and since then has moved from this conception of the 'social skin' to a more thorough development of the place of 'bodiliness' among the Kayapo and more generally in anthropological thinking (1995). James Fernandez, following his powerful treatment of metaphor and body symbolism in the Bwiti religion among the Fang in Gabon, later turned his attention to the place of the body in Bwiti explicitly with respect to developing theorizations of embodiment (Fernandez, 1990). In work on ritual healing, ritual language, and the cultural constitution of self among Catholic Charismatics in contemporary North America, Thomas Csordas elaborated earlier arguments cast in terms of rhetoric with analyses made from the standpoint of embodiment (Csordas, 1997). In her work on South Africa, Jean Comaroff (1985) refocused the traditional anthropological interest in body symbolism in the context of contemporary approaches to the analysis of political economy, and ritual healing, tracing these themes across the precolonial, colonial, and postcolonial periods. In two brief but compelling passages, Michelle Rosaldo (1984) did much to open the way for an understanding that collective symbols acquire 'power, tension, relevance, and sense' through embodiment (p. 141), and that emotions are 'embodied thoughts' (p. 143).

The theoretical crux of these new syntheses is a critique of tenacious conceptual dualities such as those between mind and body, subject and object, sex and gender, and body and embodiment. These developments must be seen in the theoretical context of the prominence since the 1970s of notions such as the interpretive turn, the linguistic turn, the move to cultures defined as systems of symbols, and concepts such as textuality, discourse, representation, and semiotics broadly conceived. Understandings of the body itself in terms of the 'metaphor of the text' is evidenced in common scholarly phrases like 'the body as text,' 'the inscription of culture on the body,' or 'reading the body.' Recent work on embodiment offers the opportunity to balance what is thus, to some, an overemphasis on representation. When this tack is chosen, a key theoretical term that comes to take its place alongside representation is 'being-in-the-world.' The latter notion, drawn from phenomenology, does not supplant representation, but offers it a dialogical partner: in brief, semiotics offers the notion of textuality in order to understand representation, and phenomenology offers the notion of embodiment in order to understand being-in-the-world. 'The body' per se, can then be construed both as a source of representations and as a ground of being-in-the-world (Csordas, 1994). Meanwhile, 'embodiment' becomes an avenue of approach to culture and self, just as textuality is an approach to the study of culture and self. Thus, to work in a 'paradigm of embodiment' is not to study anything new or different, but to address familiar topics – healing, emotion, gender, or power – from a different standpoint. There is not a special kind of data or a special method for eliciting such data, but a methodological attitude that demands attention to bodiliness even in purely verbal data such as written text, or oral interview.

Interdisciplinary Consolidation

Since the beginning of the twenty-first century, there has been an intellectual consolidation of studies on the human body, embodiment, and bodily experience across disciplines with anthropology playing a strong role. This is evident in the historically oriented reader by Lock and Farquhar (2007) with its gesture toward the increasing awareness of materiality as relevant to understanding the body, and in the collection of original and cutting edge works compiled by Mascia-Lees (2011) with its recognition of the distinction between the body and embodiment across issue ranging from cultural phenomenology to virtuality and from colonialism to impairment. Closely related volumes with a strong contribution from sociology, philosophy, and cultural studies include those edited by Forth and Crozier (2005), Moore and Kosut (2010), Pirani (2011), Weiss and Haber (1999), and Turner (2012), with critical individual articles by Gatens (1996) and Sheets-Johnstone (2009). Further evidence of the consolidation of body studies is the massive six volume, *Cultural History of the Human Body* (Crozier, 2010; Crozier and Beccalossi, 2010; Garrison, 2010; Kalof, 2010; Kalof and Bynum, 2010; Reeves, 2010; Sappol and Stephen, 2010) spanning the period from antiquity to the contemporary moment. From a number of disciplinary standpoints, significant works have appeared on embodiment and religion (Csordas, 2002, 2004), aesthetics (Johnson, 2007), and gesture (Kendon, 2004; McNeill, 2005; Noland, 2009). Particularly, intriguing is a new rethinking of the relation between mind and body that actively seek a synthesis between phenomenology and cognitive science (Chemero, 2009; Gallagher, 2005; Gibbs, 2005). Finally, an impressive body of work has been emerging from Latin America and Iberia (Esteban, 2004; Muniz, 2010, 2011; Caon, 2012; Steil and Carvalho, 2012), including a number of works emphasizing dance as a locus of embodiment studies (Citro, 2009, 2007; Citro and Aschieri, 2012). Although consolidation is an apt term for the manner in which these works define an empirical and methodological terrain, this in no way indicates a rigidification or decline into redundancy. Instead, it indicates a vibrance and surge of intellectual creativity that can be expected to yield continued scholarly advances. This can be seen as the concern with human corporality increasingly engages the concern with animality and materiality, as phenomenological and cognitive styles of understanding embodiment achieve a rapprochement, as interdisciplinary discourse continues to expand, and as an ever-growing number of topics come to be approached from the standpoint of embodiment.

Summary

In summary, the body's career in anthropology has been on an upswing. From an early anonymity as a taken-for-granted

background feature of social life, it has emerged in recent decades first as an explicit topic of anthropological research, then as a problem as its cultural and historical instability as a natural object became increasingly evident. More recently, embodiment has presented itself as an opportunity for reformulating earlier interpretations and rethinking fundamental concepts of culture and self. Through the 1990s, the problem posed by the body of the relation between representation and being-in-the-world has been an increasingly prominent site, at which anthropologists have become engaged in the wider interdisciplinary discourse of the human sciences. Relevant studies can be found under the rubrics not only of anthropology of the body, but also of medical anthropology and anthropologies of the senses, space, dance, violence, and science and technology. On a wide variety of fronts, the body continues to advance.

Abstract

The earliest stages in the evolution of the human body (2–6 Ma) involved a gradual adaptation to terrestrial bipedality through various structural modifications. Body size in these early ancestors was smaller, but sexual dimorphism larger than in modern humans. With the evolution of *Homo erectus* about 1.5–2.0 Ma, essentially modern body proportions and levels of sexual dimorphism were established. Body size reached a peak between about 50 000 and 500 000 years ago and has declined on average since then. Body shape variation among both earlier *Homo* and modern humans is strongly conditioned by climatic adaptation.

Major changes in body form have taken place during human evolution, related to the initial adoption and increasing commitment to bipedal locomotion and continuing adaptations to climatic, dietary, and other environmental factors. Although all modern humans share a similar body plan, there is still substantial variability in body size and body shape within and between populations that is in part a reflection of environmental adaptation. This article reviews the evidence for both the evolution and modern distribution of body form in humans and its behavioral and ecological significance.

The Bipedal Transformation

It is widely agreed that the transition from quadrupedal to bipedal locomotion was one of the most important innovations in human evolution; indeed, bipedality defines our lineage better than any other single characteristic (Clark, 1964; Aiello and Dean, 1990; Fleagle, 1999). Efficient bipedal locomotion requires changes in a number of anatomical characteristics, including restructuring of the lower limb and vertebral column, and other alterations. Recent evidence indicates that some form of bipedality may have been practiced by hominins as early as 6 Ma (Senut et al., 2001; Richmond and Jungers, 2008), and possibly even 7 Ma (Zollikofer et al., 2005), very close to the time when humans split off from African apes.

However, it is also becoming increasingly clear that the transition to a fully modern form of terrestrial bipedality occurred much later in hominin evolution, perhaps only with the appearance of *Homo erectus* about 1.5–1.8 Ma (Walker and Leakey, 1993; Ruff, 2008). Hominins dating from about 2.0 to 4.5 Ma, including *Ardipithecus ramidus*, *Australopithecus anamensis*, *Australopithecus africanus*, *Australopithecus garhi*, and *Australopithecus sediba*, as well as some extending more recently (between 1.2 and 2.0 Ma), including *Paranthropus robustus*, *Paranthropus boisei*, and *Homo habilis*, exhibit a mosaic of locomotor characteristics that indicate either an altered form of terrestrial bipedality and/or retained arboreal (tree climbing) capabilities. These include, in some taxa, a foot better adapted for climbing than in modern humans (Clarke and Tobias, 1995; Lovejoy et al., 2009a; Zipfel et al., 2011; DeSilva et al., 2012; Haile-Selassie et al., 2012), long and robust upper limbs and a more superiorly oriented shoulder joint, again for climbing (Clark et al., 1984; Heinrich et al., 1993; White et al., 1993; Kimbel et al., 1994; Leakey et al., 1995; McHenry and Berger, 1998; Lovejoy et al., 2009b; Ruff, 2009; Green and Alemseged, 2012), and variations in foot, hip, and pelvic structure that indicate some differences in posture during walking compared to modern humans (Ruff, 1998; Lovejoy et al., 2009c; Zipfel et al., 2011; Ruff and Higgins, 2013).

Thus, the adoption of terrestrial bipedality was gradual, and probably involved increasing reliance on this form of locomotion while still retaining the ability to use trees, e.g., for escape from predators or for food procurement. There are many theories on why and how human bipedalism evolved, including ecological and dietary shifts, and changes in social organization (for a review, see Fleagle, 2013). While distinctively human proportions of the body, such as forelimb to hindlimb size, were established by 1.5 Ma in *H. erectus* (Walker and Leakey, 1993; Ruff, 2008), within this basic body plan variations in other aspects of body size and shape are apparent throughout the more recent fossil record and among living humans.

Variation in Body Size

Body mass (weight) for fossil specimens has been estimated using various parts of the skeleton, including craniodental dimensions, but it is clear that postcranial dimensions provide the least biased and potentially most accurate means for reconstructing body size, especially in an evolutionary lineage where changes in relative tooth and cranial size have been dramatic (Pilbeam and Gould, 1974). Two basic types of methods can be distinguished: a mechanical approach, which uses features that are related to the mechanical load-bearing function of the skeleton, such as hip joint (femoral head) size, and a morphometric approach, in which features that actually reflect the size and shape of the postcranial skeleton are used (Auerbach and Ruff, 2004). For the latter, it has been shown that stature, estimated from limb bone length, and body breadth, measured across the pelvis, together provide a good estimate of body mass (Ruff, 2000; Auerbach and Ruff, 2004; Ruff et al., 2005). Correlations between

body masses determined using both techniques in the same specimens are good, indicating little bias in results (Ruff et al., 1997; Auerbach and Ruff, 2004).

Changes in estimated body mass over 6 My of human evolution are shown in Figure 1, along with a set of values for modern living humans for comparison. A total of 148 premodern individual specimens are included. In most of these, body mass was estimated from hip joint size (femoral head breadth measured directly or in a few cases estimated from acetabular breadth), using equations derived from modern humans (Ruff, 2010). In 26 cases, it was also possible to estimate body mass from stature and pelvic breadth, again using equations derived from modern humans (Ruff et al., 2005). In these specimens, an average of the two estimates was used (as in previous studies, the two techniques produced very similar results). Unlike in some previous studies (e.g., Ruff et al., 1997), no pelvic breadths were estimated, due to recent evidence that the patterning of relative pelvic breadth among fossil hominins was more complex than previously modeled (Trinkaus, 2009; Ruff, 2010). Because of the much higher density of data available for more recent periods, the data are plotted on a logarithmic temporal scale. Specimens are divided into *Homo* (*Homo* sp., *H. erectus*, and *Homo sapiens*, including Neandertals) and non-*Homo* (see earlier text for taxa). The modern living data are 53 sex-specific sample means (Ruff, 2010). Both modern and earlier data are from the Old World (except for two modern Inupiat samples) and include samples or individuals from both higher and lower latitudes as well as both sexes; all are adults.

Several trends are apparent in Figure 1. First, body size was relatively small (21–53 kg) in the earliest period of human evolution and markedly increased with the appearance of *H. erectus* at about 2 Ma. This likely coincided with a number of other biological and behavioral changes, including a complete commitment to terrestrial bipedality (also see earlier text), increased diurnal travel through open country, and possibly an increased reliance on hunting (or at least foraging range) (Wheeler, 1992; McHenry, 1994; Ruff, 2009). Note that one specimen of uncertain attribution – the pelvis from Gona, Ethiopia (Simpson et al., 2008) – falls well under the known body size range of *Homo*, further supporting its assignment to a non-*Homo* species, most likely *Australopithecus boisei* (Ruff, 2010).

The second general observation apparent from Figure 1 is that body size in premodern *Homo* was generally above the average for modern (living) human populations. The median body mass for the modern humans is 57 kg; 87% of the earlier *Homo* specimens are heavier than this, with an overall median of 68 kg (19% heavier). Part of this may be attributable to a male bias in the fossil record: of the 87 out of 113 earlier *Homo* specimens that can be reliably sexed, 63% are male. However, this pattern is evident even within sex: earlier *Homo* males average 20% heavier and females 13% heavier than modern males and females. Another possible factor is latitude: as discussed later in the text, among modern humans (and many other mammalian species) there is an ecogeographic cline of increased body mass in colder climates, and a majority of the premodern specimens in Figure 2 (especially among the later ones) are from higher latitudes. Figure 2 is a plot of temporal trends in body mass over the past 35 000 years among only higher-latitude males (mainly European),

Figure 1 Temporal changes in body mass (weight) over the past 6 My of hominin evolution (note logarithmic time scale). Body masses in fossil specimens determined primarily from femoral head size (see text). Filled triangles: non-*Homo* species; open triangle: Gona specimen, of uncertain taxonomy (see Ruff, 2010); open circles: *Homo;* x's: modern humans (worldwide sample of male and female population means). Quadratic equation used to fit regression line through premodern *Homo*. Dotted line indicates modern median.

Figure 2 Change in body mass among higher-latitude males over the past 35 000 years. Body masses and symbols as in **Figure 1**. Linear regression fit through premodern sample. Dotted line indicates modern median.

compared to modern higher-latitude males. The linear regression on time (not including the modern data) is negative and near-significant ($p = .09$). Higher-latitude males in the Early-Middle Upper Paleolithic (16 000–35 000 years ago) average about 9% heavier than modern higher-latitude males. Median body mass in males from the Late Upper Paleolithic (10 000–15 000 years ago) is very similar to that of the living sample.

This highlights another aspect of temporal trends in body size: maximum body mass was apparently reached in the late Middle and early Late Pleistocene, i.e., between about 500 000 and 50 000 years ago, after which it declined to modern human values by the end of the Pleistocene (10 000 years ago). Thus, a quadratic curve best fits the premodern *Homo* data in Figure 1 (as determined by the akaike information criterion (AIC)). Increased body size during the late Middle and early Late Pleistocene may be related to foraging strategies such as an increase in big game hunting (e.g., Thieme, 1997) as well as more common occupation of high-latitude environments (see below). The later decrease in body size may be attributable to changing technology, resource exploitation, and demographic shifts in the terminal Pleistocene that no longer selected as strongly for large body size (Frayer, 1984; Richards et al., 2001; Milisauskas, 2002; Lagerlöf, 2007). There is evidence that average body size continued to decline through the Neolithic, at least in Europe (Frayer, 1984; Niskanen et al., 2012), perhaps because of decreased nutritional quality and/or increased disease transmission associated with the agricultural revolution (Cohen and Armelagos, 1984). Body size has increased dramatically over the past century in many populations, probably due to improvements in the environment (Eveleth and Tanner, 1990; Katzmarzyk and Leonard, 1998), although the opposite trend has been observed in some disadvantaged populations (Tobias, 1985).

Sexual dimorphism (i.e., differences between sexes) in body size is another important characteristic of a species with many potential behavioral and ecological implications (e.g., McHenry, 1994; Plavcan and Van Schaik, 1997). Recent analyses of sexual dimorphism in body mass, using methods similar to those described earlier, indicate elevated levels of dimorphism in hominin taxa prior to the appearance of *H. erectus*, with an average male/female ratio of about 1.3 or higher (Ruff, 2002, 2010). Species within *Homo* are characterized by reduced levels of dimorphism, similar to those of modern humans, i.e., an average male/female ratio of about 1.1–1.2. This implies changes in ecology and behavior with the evolution of *Homo*. It also implies that in at least some aspects of social organization, early *Homo* may not have differed markedly from modern hunter-gatherers.

Variation in Body Shape

One aspect of the environment that has probably had a profound effect on human body shape is climate. Systematic relationships between climate and body form among homeothermic animals have been recognized for more than a century and have been codified as Bergmann's and Allen's ecogeographical 'Rules' (Mayr, 1963). Bergmann's Rule states that within a species or closely related group of species, populations living in colder climates will be larger in body mass than those in warmer climates, while Allen's Rule states that colder climates will be associated with shorter extremities and warmer climates with longer extremities. Both of these observations are actually consequences of a more general relationship between body mass and body surface area, in which both a larger body mass and relatively shorter extremities decrease the ratio of surface area to body mass, thus conserving heat, and vice versa. The same principle can also be applied to the overall shape of the human trunk: it can be shown that an absolutely wide trunk (and thus wide body) will lead to a decreased surface area/body mass ratio, regardless of body height, while an absolutely narrow trunk will lead to an increase in the ratio, explaining the narrower bodies of tropical populations and wider bodies of arctic populations (Ruff, 1994).

Ecogeographical clines that conform to physiological (climatic) expectations have been demonstrated for many aspects of living human body form, including body mass, body breadth, relative limb length, and direct estimates of surface area to body mass (Roberts, 1978; Ruff, 1994; Cowgill et al., 2012). It is more difficult to evaluate such morphological variability in our fossil ancestors, but recent paleoanthropological discoveries combined with developments in methodology have provided some new insights.

All early hominins apparently had relatively wide bodies compared to humans living in the same areas today (Ruff, 2010), which may be the result of an altered birth process in which the neonate's head did not rotate during birth as it does today (Tague and Lovejoy, 1986; Ruff, 1995, 2010). However, even among earlier human ancestors, there is evidence for latitudinal variation in body breadth similar to that observed among modern humans, with specimens from higher latitudes exhibiting wider bodies than those from lower latitudes (Ruff, 2010). Relative limb length is also affected by locomotion (*see* Section The Bipedal Transformation), so this aspect of morphology is more difficult to evaluate in terms of climatic adaptation per se in early hominins. However, among *H. erectus* and later taxa, where terrestrial bipedality was well established, lower-latitude specimens are characterized by relatively longer extremities, and higher-latitude specimens by shorter extremities, again matching ecogeographic predictions (Trinkaus, 1981; Ruff and Walker, 1993; Ruff, 1994; Holliday, 1997; Rosenberg et al., 2006). In fact, in some ways earlier humans appear to exhibit extreme morphological adaptations to climate, i.e., 'hyperarctic' and 'hypertropical' body forms (Ruff and Walker, 1993; Ruff, 1994; Holliday, 1997; Weaver, 2003), possibly as a result of less efficient cultural buffering against the environment.

Such observations can also inform interpretations of past population movements and in situ adaptations. Occupants of Western Europe during the Middle and early Late Pleistocene were subjected to periodic episodes of extreme cold, i.e., glaciations; cool conditions prevailed even during some interglacial periods (Trinkaus et al., 1999). Body breadths were correspondingly wide, either absolutely or relative to stature, and limb lengths relatively short (Ruff, 1994; Holliday, 1997; Arsuaga et al., 1999; Ruff, 2010; Walker et al., 2011a,b). About 25 000–45 000 years ago, archaic humans (Neandertals) in Europe were gradually replaced by 'early anatomically

modern humans' (EAM) (Finlayson et al., 2006; Benazzi et al., 2011; Higham et al., 2011). These EAM populations were much taller, relatively less wide-bodied, and had relatively longer limbs (Ruff, 1994; Holliday, 1997), all evidence of a more tropical origin. Over time, the body proportions of European EAMs became less 'tropical,' increasing in relative body breadth and decreasing in relative limb length; until by the Late Upper Paleolithic (10 000–19 000 years ago), they were essentially indistinguishable from those of modern Europeans (Ruff, 1994; Holliday, 1997). This change can be seen, at least in part, as evidence of environmental adaptation to colder climatic conditions following migration from farther south, i.e., northeast African and/or the Middle East (White et al., 2003). Anatomical evidence of previous climatic adaptation to cold conditions followed by a migration over the Bering Sea Land Bridge is also apparent among early inhabitants of the New World, shedding new light on the origins of these populations (Ruff, 1994; Auerbach, 2012).

Body Size as a Baseline for Other Comparisons

In addition to its biological and cultural significance, body size is important in human evolutionary studies because it is often used as a 'denominator' against which to evaluate other physical traits. One prime example is brain size, which is commonly expressed as a ratio against body mass, or encephalization quotient (EQ) (e.g., Pilbeam and Gould, 1974). EQ increased in early *Homo* (1.5–2.0 Ma) relative to earlier taxa, but then remained constant for at least a million years (to 0.5 Ma), after which it increased again, exponentially, to modern values (McHenry, 1994; Ruff et al., 1997). Skeletal robusticity has also been evaluated relative to body size, and shown to follow an inverse trend relative to brain size (Ruff et al., 1993), which may reflect the increasing importance of technology and decreasing selective advantage of physical strength among modern humans.

Finally, the body size of earlier humans can be used as a baseline for contextualizing the health of modern populations. Comparing present-day measures of stature and body mass with those of ancestral populations may give better estimates of potential body size limits and provide guidance in setting nutritional and other health standards (WHO, 1995).

Abstract

The history of the body continues to be a sensitive subject. Although the body was considered to be a 'stable experience' (and as such, not part of cultural evolution and historical change), bodily experiences of humans were never absent from historiography. Nonetheless, a continuous, conscious, explicit reflection on the role of the body only began four decades ago across the social sciences and humanities. It was only when the static, biological, and naturalistic idea of the body started being criticized that body-related questions were addressed among historians and constituted a new field of research. As such, it is sometimes seen as an interdisciplinary meeting point of several different approaches (discourse analysis, semiotics, gender studies, cultural studies, science and technology studies, etc.); others consider it an independent subdiscipline of history. From a historico-scientific perspective, there exist a number of arguments in favor of highlighting the shift of paradigms that took place in the 1970s, and asking how a new, theoretically based examination of the body has influenced older fields of research like demography and social history. This article addresses the problem of corporeality and the two dominant approaches to the history of the body, the continuities and the shift of paradigms, current fields of research, and current controversies and prospects.

The Problem of Corporeality and the Two Approaches to the History of the Body

The pathbreaking essay 'Dialectic of Enlightenment,' first published in 1947, includes a text fragment entitled 'The interest in the body.' There, Max Horkheimer and Theodor W. Adorno argued that the 'love–hate relationship to the body' (2000: 289) and the rejection of corporeality were the hidden subtexts of modern society. This oblivion of the body was related to the long-lived dichotomy between body and soul, i.e., with the Cartesian opposition of *res extensa* and *res cogitans*, which met with such success for many centuries. The consequence was the exclusion of the body from social processes and its naturalization (Danto, 1999). As the progress of secularization accelerated in the eighteenth century, mankind learned to consider society, its institutions, and modes of representation as historical realities which man himself had called into existence. The 'modern body' however was taken for granted and considered to be outside historical evolution: As a 'stable experience' (Armstrong, 1983) it could even be defined as the antithesis of cultural change. Because it was not man-made, it could be of no interest as an object of historical interpretation. In the nineteenth and twentieth centuries, the body became a privileged object of experimental research, labor techniques, and medical interventions. In epistemological terms, it remained an immutable biological given, a bastion of nature that opposed a limit to the general historicizing of thought.

Since the middle of the nineteenth century, this 'natural body' had become the stronghold of evolutionary biology, while a number of other disciplines (anatomy, physiology, biomedicine, physical anthropology, occupational and nutritional science, hygiene, molecular biology, genetics, etc.) individually began to research this seemingly inalterable physical entity of the *Homo sapiens*, using quantitative measures, exact methods, and laboratory experiments in order to produce identification techniques (Groebner, 2007) and medical knowledge (Foucault, 2008). Safeguarding collective security and the optimization of personal fitness were the main objectives of their efforts. Individuals should be protected, rationalized, normalized, healed, or maintained in good health. The fact that the body was thought to be independent of culture and that, at the same time, the modern age was literally obsessed by the impact of carnal corporeality on both individuals and society, explains the existence of a 'love–hate relationship' toward the body, diagnosed by Critical Theory.

Against this background, the history of the body proves to be a sensitive subject. However, it does not deal exclusively with the presence of the body in history. At this point, it is necessary to define two different concepts:

- On the one hand, it must be stressed that the body was never absent from historiography. "Either 'the body' is not really a subject of its own, or it contains nearly all other subjects" (Bynum, 1996). Historical works are full of phenomena which would be impossible to describe without frequent references to the human body: Demographers work with vital statistics to produce indicators on birth rate, morbidity or mortality; some of these studies reduce the drama of life to quantitative relationships. Other authors (Imhof, 1992) combined empirical findings on the extension of the average life expectancy and the tendency toward a decline in the number of children with historico-cultural questions, in which the experience of the body and the meaning of life were omnipresent. Neither the history of political philosophy nor the history of societies and mentalities, as suggested by the Annales historians in France since the 1920s, would make any sense without the presence of the body. As early as 1938, Lucien Febvre suggested writing a history of sensitivity and of the changing 'systems of emotions' in order to understand human agency (Febvre, 1941).
- On the other hand, it is clear that a continuous, conscious, explicit reflection on the role of the body only began four decades ago in social sciences and humanities. For it is only since then that a static, biological, and naturalistic idea of the body started being criticized in a theoretically

productive way. Since then, the idea of the historicity of the body developed a transformative momentum in a newly constituted field of research. As such, it is sometimes seen as an interdisciplinary meeting point of several different approaches (discourse analysis, semiotics, gender studies, cultural studies, historical anthropology, science and technology studies, etc.), whereas others consider it an independent subdiscipline of history.

These two concepts of 'body history' give rise to frequent misunderstandings. While one party insists on the innovative potential that body history has been proved to have since the 1970s, the other party, mostly traditional social historians, dismisses it as a fashion trend that conceals the evidence that history as a science focusing on the socio-cultural interaction of human beings, has always been body history. From a historico-scientific perspective, however, there exist a number of arguments in favor of highlighting the shift of paradigms that took place in the 1970s, and asking how this new, theoretically based examination of the body has influenced older fields of research like demography, social and medical history as well as gender and environmental studies (Corbin et al., 2005).

Continuities, Shift of Paradigms, and New Topics

The historicizing of the body can be split up into five phases (which are not clearly distinct, but overlap frequently with one another).

In the first phase, which lasted until the early 1970s, a number of innovative studies looked at the human body and the imagery that had crystallized around it as objects of theoretically elaborated analyses. Later, they became 'classics' in the domain, although their initial intention had nothing to do with the new specialty named 'history of the body,' which started emerging in the 1970s. The historical studies concentrated principally on the Middle Ages and the early modern era, whereas anthropology, philosophy, and psychoanalysis dared to delve into contemporary phenomena. Some of the most significant works of this period are Sigmund Freud's *Civilization and Its Discontents* (1929/30), whose central theme is the extension of the body with the help of technical artifacts and the promotion of the human being to a 'prosthetic God' – a thesis further developed by Marshall McLuhan with his understand of media as 'extensions of man'; Marcel Mauss' *Techniques of the Body* (1935), in which the body is analyzed as the first and most natural instrument at man's disposal; Paul Valéry's *Problem of the Three Bodies* (1943), which looks into the various, parallel ways of speaking of the body; Maurice Merleau-Ponty's *Phenomenology of Perception* (1945); as well as Samuel Todes *The Human Body as Material Subject of the World* (written in 1963), which deal with the body as the condition of awareness, in compliance with a philosophy of finiteness. Ernst H. Kantorowicz' in *The King's Two Bodies* (1957), examines the political theology of the Middle Ages and looks at the mystical fiction of an immortal 'political body' existing in parallel to the mortal 'natural body' of the King.

A second phase began in the 1960s and was blossoming in the 1970s. Theoretical thinking was accompanied by the removal of the body's taboos in the alternative culture of the time. Remaining in a traditional trajectory, social history focused on the medical profession whose power was imposed on the bodies of broad strata of the population. This view of a 'medicalization' (analyzed both from the top down and from the bottom up) was challenged by Michel Foucault, who epistemologically dissipated the 'medical,' as perceived by social historians, into a 'microphysics of power.' Particularly with *The Birth of the Clinic* (1963) and *Discipline and Punish: The Birth of the Prison* (1975) Foucault became the deciding authority of a new approach. Another seminal contribution was Mary Douglas' *The Two Bodies* (1970), in which the author examines the metaphorical relationships and cognitive interactions between the body as a social construction and the individual physical body. The new studies of the human body were based on the thesis of a constant interaction between knowledge and power. In the late 1970s, Foucault's concepts of a bio-power and of a political economy of the body were set up against a liberal-Marxist scenario of disciplinary force, which represses the body. Contrary to the assumption of a 'disciplinary society' (in which the subject is oppressed by power), in Foucault's view the body is produced by knowledge-based power, which shapes everyday practices and generates regimes of visibility and discourses. In the concept of a 'normalizing society,' the body is the medium which binds together the macroorganization of power and the micro-practices through which social structures are stabilized. This perspective is directly connected to Norbert Elias' opus magnum, *The Process of Civilization*, which was published in the late 1930s but met with significant success only three decades later. Elias promoted the concept of the individual internalization of social constraints ('force to force oneself'). The 'cultural production' and the 'social shaping' of a modern human being is defined by Elias in terms of an ever-growing, individual self-control, mainly through the decoupling of emotions and bodily expressions. The 1970s were far away from being homogeneous. They also saw the publication of interesting studies in various domains of social sciences, notably by Helmuth Plessner (philosophical anthropology of the senses); Heinrich Schipperges (outlines for a philosophy of the body); Dietmar Kamper and Christoph Wulf (return of the body and fading of the senses); Rudolf zur Lippe (on the own body) which deals with 'the economy of life'; and many others.

The third phase, the displacement of the 'social' by the 'cultural' and the concomitant attention to the body, gained momentum. This shift was strongly influenced by gender studies and the feminist criticism of science, which admitted gender as a category for analysis and introduced new standards into body history. Thanks to Yvonne Verdier, Carolyn Bynum, Ludmilla Jordanowa, Marie-Christine Pouchelle, and many others, new interpretations of the body appeared at the end of the 1970s, emphasizing its relation to gender history and clearing the ground for a far-reaching, methodologically highly interesting discussion. In Germany, these endeavors are connected above all to the name of Barbara Duden, who published an innovative study, *The Woman Beneath the Skin: A Doctor's Patients in Eighteenth-Century Germany*, in 1987. In this book about the interior, invisible corporeality of women in Eisenach (Germany) and their doctor Johann Storch, the historian and sociologist Barbara Duden examines the sociogenesis of the modern body in relation to a history of the body's receptivity to

experiences. She analyzes the 'loss of control over the body' as a gate toward physical experience and speaks in favor of a "hermeneutic interpretation of the body's reality in the past": Although we cannot use 'our body' (which we have 'possessed' since the eighteenth century), as a bridge to interpret the experiences of people before the Enlightenment, the corporeality of every human existence gives us access to the context in which women and men experienced feelings in the past.

The fourth phase is characterized by a turn toward discursive, semiotic, and performative approaches and marks the beginning of a new era in the history of the body, which also led to a post-structuralist reassessment of key authors of the 1960s, especially of Foucault, whose impact on cultural theory was deepened considerably after his death in 1984 (Fassin and Memmi, 2004). The 90s saw new authors coming up: in particular, Thomas W. Laqueur's *Making Sex* (1990) and Judith Butler's *Bodies That Matter* (1993) fulfilled the linguistic turn in body history and provoked the supporters of the traditional, experience-based study of corporeality. Laqueur examines the constitution of the body through discourse and action; from this point of view, sex is "situational; it is explicable only within the context of battles over gender and power." In contrast, Butler – who, after her book was published, was wrongly considered to be an advocate of 'disembodiment' – criticized the subject-centered constructionist approach by relating the materiality of the body to the performativity of gender: "What I would propose in place of these conceptions of construction is a return to the notion of matter (…) as a process of materialization that stabilizes over time to produce the effect of boundary, fixity, and surface we call matter" (Butler, 1993; Lorenz, 2000). Notably the debate on AIDS provoked a crisis of representation and fostered a new sensibility of the materiality of the human body (Cooter and Stein, 2008).

Since the turn of the century (the fifth phase) a 'somatic turn' has questioned the hitherto antiessentialist and representationalist understanding of the body. As Chapter 5 will argue, the growing tendency to criticize the "dissolving of the body into speech" (Bynum, 1996) is however not equipollent to a relapse in an unreflecting neoessentialism of corporeality but rather the recognition of the uncircumventable materiality of the body (Cooter, 2010).

Fields of Research and Types of Analysis

For a long time, researchers in the field of body history were not sure whether they were looking into a completely new domain or whether they had simply discovered a new and interesting perspective, which offered the possibility of an innovative approach toward well-known social phenomena. The question becomes more complex: from the very beginning, body history was the fruit of interdisciplinary efforts, which can have two consequences – namely losses of clarity due to frictions between the disciplines; and the positive effects of synergy (cf among others the *Fragments for a History of the Human Body*, Feher, 1984). Authors who had already attempted a systematic approach to body history in the mid-1980s presented an overview of the broad portion of research based on social sciences. From a phenomenological point of view, Bryan Turner (1984) describes four tasks with which any social organization confronts bodies (and vice versa): (1) the reproduction of populations in time, (2) the regulation of bodies in space, (3) the constraints of the 'interior' body through control and discipline, and (4) the representation of the 'exterior' body in the symbolic space of the society. John O'Neill's *Five Bodies* (1985) provides an alternative, more institution-based conceptualization, distinguishing (1) the world's body, (2) social bodies, (3) the political body, (4) consumer bodies, and (5) medical bodies.

In the narrower field of historiography, although there have been frequent variations in the main fields of interest, one can observe an obvious concentration of research on the Middle Ages and the Early Modern Era. Starvation and fasting, posture, body language, clothing habits, disciplining of the human body through the art of dancing, training of soldiers, seduction, sexuality, pregnancy and childbearing: these and other themes were examined in the light of cultural anthropology and iconography and resulted in new views on everyday life and bodily experiences in past centuries. The *Education of the Senses* (Peter Gay), the history of *Sensory Awareness* (Rudolf zur Lippe), and an *Anthropology of the Senses* (Febvre, 1941) turned out to be especially interesting fields of research. The conflict about the hierarchy of the senses, which began in antiquity, the theses of a 'mythopoetical constitution of the individual' (Hartmut Böhme) and of a 'privilege of the eye' in the present time (Virilio, 1996) remain of symptomatic value. The history of sensory experience is closely linked with the history of the 'wisdom and the remembering of the body': as a materialized matrix for inscriptions of cultural experience, the body is a part of the memory of a society. Step by step, performativity relates the signification process with the materiality of the body. It is the reiteration of practices and the regulation of discourses which generate the feeling of continuity and reliability of the 'real world.'

Another area that offers many possibilities for research is the history of the perception of the body and of body-related imagery and esthetics. In the course of secularization, the image of the body as a 'wheelwork,' whose perfect functioning was the proof of God's Creation, was replaced by the idea of a machine working according to the laws of nature (with a male connotation: the man is considered to be the standard human being). Along with this evolution came the growing conviction that the body is a closed entity and the medieval image of a 'grotesque,' open body (Bakhtin, 1981/1930) was gradually replaced by the modern, closed 'Skin-Self' (Anzieu, 1989). This evidence depended on new schemes of visibility: Barbara Stafford describes this historical shift toward visualization with the help of somatic metaphors and she points out the important role played by the visual arts when it came to solving the representational problem of the embodiment or personification of knowledge. Crucial for this development was the eighteenth century, which saw the breakthrough of a 'possessive individualism' in the perception of the body. This resulted in a "degradation of the notion of a self extended into a unique and inviolable corporeal volume, to one in which the self only loosely possessed a body" (Karl Figlio). The problem for the historical investigation into this body, which we possess and which is analyzed by science, "is not how something that is obvious today had remained hidden for so long, but how the body had become so evident in the first place" (Armstrong,

1983). Thanks to the modern perceptions of the body, new ways of seeing collective bodies were also brought to the fore. Jacob Rogozinski (2010) showed that the incarnation of the individual in an all-embracing global body is an old phenomenon, but in the nineteenth and twentieth centuries, the political hypostatization of this collective body became still stronger. While society depended more and more on technology, strengthening the thesis that social cohesion results from the linking-up of the elements of society by a powerful communicative 'nervous system,' nationalism encouraged the phantasm of a 'body of the people' and of a 'blood community.' For example, the imagery of the *Body of the Nation* (Goltermann, 1998) proved to be mediated by the practice of male gynmastics, which aims at the appropriation of the national order through individuals and social groups.

Medicine, dietetics inspired from humoral theory and the modern conception of hygiene, which emerged in the middle of the nineteenth century, also offer fertile ground for research in body history. Traditional, epidemiological approaches of research on disease are completed by analyses of illness, suffering, pain, and death of human beings, who were increasingly considered as patients in the course of the nineteenth century, and thus submitted to medical experts' power of definition.

A similar process of professionalization and scientization took place in the areas of occupational and nutritional science. The interaction of physiology and the industrial society show, for instance, how epistemic regimes, technological artifacts, and social interests are intertwined in the production of knowledge; and how the knowledge thus produced facilitates the appearance of individuals who consider their bodies as 'instruments of self-perfection' (Sarasin, 2001). In this context, the modification of individuals' self-images under the influence of scientific knowledge is studied in parallel with the unwillingness of the body faced with the exigencies of a working society, which is subject to the paradigms of efficiency and rationalization. In the leisure society of the postwar period, in which the body functions as a site of consumption, the questions arising from an invariably incomplete integration of the individual body into the social structure remain to be answered by further historical research.

Body History Reloaded in 2000

Body history was always entangled by normative judgments and was the object of emotional stakes. Generally, in social sciences and humanities, experience-based concepts of the body implying a lived corporeality are being challenged by poststructuralist–deconstructivist models that consider the body primarily as a discoursive effect or a product of the knowledge-power-complex accumulated since the Enlightenment. Nonetheless, around 2000, there was a consensus that it was essential to overcome the opposition of 'discourse' and 'experience' (Canning, 1994). These debates frequently overlook the fact that the history of the body is in the midst of the fundamental discussion on the blurring of the boundaries between nature and culture. The ontological status of the traditional categories 'natural' and 'social' has become a critical question and this makes it obvious to consider the products of technology – and therefore the world we live in – as hybrid artifacts.

From this point of view, the human body, too, would be a hybrid, i.e., a 'crossbreed' in which social, technological, cultural, and natural components cannot be held apart with certainty. The materiality of the body plays a crucial role in this debate. This is obvious in disciplines, such as biomedicine, cognitive sciences (CS), and artificial intelligence (AI), which lie in a paradoxical area of tension between hyperembodiment and disembodiment: while scientists in the domain of AI start out from the assumption that intelligence can be modeled only on a material, body-bound, base, which implies that machines that have 'emerging properties' and therefore the ability of learning must by definition be 'techno-bodies' (Lakoff et al., 1999), and other authors (e.g., Flusser, 1994) follow the principle 'from the subject to the project' to develop visions according to which the concept of the body has become a creative activity of mankind, escaping the 'blind contingencies of nature.' It is essential to realize that information technology, genetic engineering, and xenotransplantation have made natural boundaries permeable and put mankind in a position to gain control over the evolutionary process of life, which started billions of years ago.

It is precisely because of these perspectives, which are technocratic and playful at once, that the findings of body history have gained capital importance. Although they are incomparable for various reasons, the concepts of the body suggested by biomedicine, information technology, and genetic engineering are in compliance with the more modern approaches of the social sciences and humanities concerning the thesis that the body is not an invariable, unchangeable entity, independent of time and history. The willingness to reassess the body as a product of society and the readiness to think about how bodies are culturally constructed or constituted, became a salient feature of historical research on the body. If historiography demonstrates that bodies were always modeled by culture, this means that scientific and technological interventions on the physiology and (for the time to come) in the genome of the human being are nothing new in principle: they are simply an intensification of a traditional way of using bodies.

In this sense, Haraway (1991) pleads in favor of a curious and innovative application of the new possibilities offered by technology; she sees the creation of natural–cultural hybrids as a promising path toward the creative self-realization of mankind. This 'Cyborg-optimism' has been contradicted. Distancing herself from technocratic feasibility fantasies, Barbara Duden proposes that although human beings are partially formed by culture, the somatic fundaments of life are an inescapable condition of their existence. Based on the paradigm of a 'historical somatology,' the examination of the 'time-bound forms of experiencing corporeality' concentrates on the relation of human beings to their body, which changes in the course of history, as a *sine qua non* of experience. Such an approach considers the current colonization of the body by science and technology as an unprecedented process and an attack on the human condition itself. Duden remains skeptical of the *mythopoesis* of a technology which models the desires of individuals in such a way that they anticipate the possibilities of science and technology.

New Trends and Topics in the Twenty-First Century

Since the advent of the twenty-first century the problems of how to understand the intricate process of the cultural construction of reality and investigate the historicity of the human body have been radicalized. Two tendencies are at the center of attention.

On the one hand the neoliberal mode of the subjectivization strengthened both the evaluation of the educational attainments and the state of the body in terms of 'Capital' (and consequently, as a problem of 'pay-back periods' and 'return on investment'). The popular resonance of the human capital theory, which was launched in economic science in the early 1960s, became tremendously successful after 1980, paralleled by an increased personal 'will to health.' The human being became cognitively and corporeally an investment sphere, a development which has been problematized in different and conflicting ways. In the first decade of the twenty-first century, the transformation of the Pursuit of Happiness (as the rationale of the 'American Way of Life,' which was imitated on a worldwide scale after World War Two) into a Pursuit of Perfection (Rothman and Rothman, 2003) became tangible, encompassing medical-enhancement techniques using surgical procedures and drugs (Serlin, 2004). The phantom of perfectibility embraces the body which becomes a malleable entity subjected to a history of its own. A large number of studies in the history of science and in art history have tracked down the endeavor to realize an optimal physiological functioning and the best possible esthetic performance of the human body (e.g., Hau, 2003).

On the other hand, and thus related, a comeback of an essentialist approach can be observed. This somatic turn was a swing reaction against the linguistic turn. Against the representationalism, put forward by the constructivist theories of the 1980s and the 1990s, emphasis was now laid on physicality, related with materiality, experience, and practice. Such a view was already proposed (earlier than its time) in the 1980s by Barbara Duden and Caroline Bynum who criticized the trend toward de-essentialization. The correlate of the emergence of a new regime of truth based in corporeality, was the interest in the 'really lived body' (Ruggiero, 2004).

These two shifts toward subjectivation and soma have theoretically valorized Foucault's concepts of the technologies of the self and of biopolitics (Foucault, 2008). Since the 1960s, Foucault has advocated a constructivist perspective on society; mean while he has criticized the reduction of reality to language and symbolic operations. He thus combined in a seminal way a constructivist approach to society and an ontological view of history (Cooter, 2010; Smith, 2007; Hacking, 2002).

This also allowed the historicizing of the relationship between personal identity and body concepts. Experienced corporeality is no longer considered to be an *explanans* to self-perceptions, but an *explanandum* i.e., something that has to be explained. The nature–nurture dichotomy and the normative juxtaposition of salvific progress and frightful threat is subverted by a new understanding of the ambiguous effects of technologies. Nicolas Rose' concept of a 'Biocitizenship' should not be confounded with biological determinism. Instead of being a natural determinant, biology turns out to be a moral commitment. People are expected to comply self-paced with the possibilities and promises of modern medicine and genetics. The crux of such utilitarian behavior is that on an aggregate level, the mode of the free choice produces flexible standards and moving norms, thereby retroacting on personal decision-making. When citizens are required to take self-governed responsibility for their genetic constitution and their neurochemical selves, then every individual who rejects that onus becomes a burden on society. Under such conditions, the individual person is transformed into a competitive entrepreneur of him/herself and can no longer argue the unavailability of his/her body. If he/she is not willing to fulfill his/her duty, he/she will be socially discriminated or penalized financially. On a normative level, a fusion of body, esthetics, and morality will be brought into operation.

As to the areas of historical and interdisciplinary research, five lines of research have become important since the beginning of the twenty-first century. First, there is a focus on the ecology of the human body that is analyzed in its multifarious interactions with its environment. Architecture, settlement patterns, urban designs, social structures, mobility behavior, and environmental pollution become important categories of an analysis of changes in perceptions of the body and bodily performances in history (Floyd-Wilson and Sullivan, 2007). A second focal point is post-colonial studies, especially the concept of 'critical whiteness' which refers to body-related perceptions of both the colonists and the colonized (Lopez, 2005; Olsén, 2011). An analogue problem is addressed with the term 'subaltern,' suggested by Gayatri Spivak to denominate the ambiguous forms of body-mediated political power. Spivak (2010) is critical toward an unhistorical essentialism. Nonetheless she advocates the use of a 'strategic essentialism,' i.e., a form of self-assertion in asymmetric power relations that propagate one 'We,' thereby trying to accept the diversity of voices in each group. In the third field we find disability studies examining the changing social interaction and the normative reciprocity between 'normal' and 'handicapped' individuals from the perspective of the latter (Watson et al., 2012). The growing acceptance of sign language demonstrates a sustainable shift in the definition of disability and a normalization of the status of people hitherto judged to be 'disabled.' In including categories like 'monsters' and 'freaks' (Stammberger, 2011), the field offers deep insights in the changing tangible and invisible restrictions, respective limitations contained in the norms and institutions of a society, as well as the dynamics of access and exclusion in all social institutions.

The fourth and fifth foci are closely related. The fourth relates to Robotics, which represents both an expanding field of current electronic-mechanical research and a topic of historical inquiry. The thesis that human intelligence and feeling are 'embodied,' has led the designers of robots away from 'clever algorithms' to morphological designs and materials. The 'Companions for Citizens'-project is aimed at the development of humanoids, which combine a high degree of thinking with (simulated) emotional traits and become reliable and bearable helpers in many everyday situations,

especially for older people. Concomitantly, the history of androids, robots, and golems has received a new boost and the long-lasting visions of a man-made man or an artificial invader (from the Golem via Faust/Frankenstein to the Blade Runner replicants, etc.) have achieved an upturn (e.g., De la Peña, 2003; Muri, 2007).

The most provoking (the fifth) research area is neuroscience which includes not only highly sophisticated Magnetic Resonance Imaging (MRI), but also the proliferation of colorful brain pictures in mass media and popular culture. From the outset, these widespread and inherently contradictory research approaches have been confronted with a historically and philosophically informed reflection on a materialistic monism (or a monistic materialism) (Danto, 1999; Hagner, 2008). A strong argument is bound to the fact that the most popular criticism of Cartesian dualism lost its innocence long ago. Already in the late nineteenth century, an antirationalist, rather occult 'holistic approach,' combined with a dull rhetoric of 'unity' has threatened Cartesian rationalists. At the turn of the twenty-first century, reductionist concepts have taken its place. In *Mind Time* (2004) the neuroscientist Benjamin Libet argues against his false followers that there is no sound reason for reducing consciousness on a neural substrate which is a necessary, though not a sufficient condition for symbolic interaction and language. Cultural evolution cannot be wrapped up either in neural encoding/decoding nor in neural circuits. The assumption that cognitive capacities are nothing more than 'ghosts in the machine' reproduces instead in a paradoxical way, the Cartesian dualism.

The body history problem needs a more subtle sublation of this binary opposition which also aims at overcoming the deeply ingrained nature–culture distinction. Already now, two points are clear: in the first place, the plasticity and malleability of the human brain supports the assumption that the neuronal substrate is shaped by social practices, cultural techniques, and symbolic codes. Learning and exercising changes cerebral networks to a degree that makes the idea of a 'natural brain' fallacious. Research projects using functional imaging techniques may show 'what happens where' in the brain. But neither the relationship between structure and function nor the temporal alteration of such operations can be adequately apprehended so far. There is no reason to believe that forthcoming neurobiological research will end up in a biological essentialism. Secondly it is obvious that new approaches of a body history can only be developed via a crosstalk involving philosophy, cultural anthropology, theory of emotions, and brain research.

Altogether the body and its 'polyphonic history' (Peter Burke) remains in the twenty-first century also, a preferential site for interdisciplinary studies and cultural analysis. The love–hate relationship mentioned by Horkheimer/Adorno is still present in many practices and discourses. There is however an endeavor to accept challenge, both epistemologically and empirically, of writing the history of the body in a more serene way, thereby focusing on the concrete, mortal human body, without forgetting that the corporeal existence of human beings will never be independent of the empire of signs, which is permanently created and transformed by cultural change.

Body Image

Abstract

Body image is a multifaceted construct which is central to an individual's self-concept, and critical to mental health and general well-being. Given our increasingly appearance-focused culture, body image concerns are now reported by both women and men across the life span. This article examines the different components of body image and prevalence of body dissatisfaction, and provides examples of measures that have been developed to assess these constructs. It also examines the main factors that shape body image related to age and gender. The nature of programs to prevent body image problems, particularly at school and policy levels, is also discussed.

Introduction

Body image is a multidimensional construct encompassing perceptions, attitudes, beliefs, feelings, and behaviors regarding one's appearance (Cash, 2004). Over a century of research on the topic has advanced the field of body image from its initial conception as a means of describing neuropathological observations in brain-injury patients, to current conceptualizations that comprise perceptual, attitudinal, cognitive, and behavioral facets. Perceptual body image refers to the accuracy with which individuals perceive their body size, whereas the attitudinal or affective component of body image relates to the satisfaction and feelings that individuals have toward their body and appearance. The cognitive dimension refers to the thoughts and beliefs that individuals have concerning their body shape and appearance. Lastly, the behavioral component examines specific behaviors, such habitual body checking, and avoidance of mirrors and public situations (Thompson and van den Berg, 2002).

Body image is not an objective evaluation of one's appearance or body. Rather, it is highly subject to change, and is shaped by the acquisition of new information (Grogan, 2008). As such, the 'image' held of one's body may be quite different from the reality of a person's body shape. A disparity between an individual's perceived body shape and his or her ideal body shape or size is proposed to result in body image dissatisfaction. It can range from a mild dislike of a particular body characteristic to intense distress associated with a desire to change the body. It may focus on a particular part of the body, or may relate to the overall appearance, weight, shape, or muscularity of the body.

To fully understand the multifaceted nature of body image, it is necessary to look beyond the individual, and understand the social context underlying the development of body image. In Western cultures, a great deal of importance is placed on physical appearance. This has been the case for women for many years, and in the last 20 years has increasingly become the case for men. Individuals are constantly faced with sociocultural pressures that promote and reinforce a narrow ideal of what is considered attractive and desirable. These sociocultural messages create unattainable standards for most individuals to achieve. This is a major reason why a substantial proportion of women and girls, and increasingly men and boys, develop negative feelings about their bodies. It is also a reason why body dissatisfaction is now one of the most significant health concerns for many individuals living in Western countries.

Body image plays a critical role in the development of both physical and psychological health. While positive body image fosters mental health and general well-being, poor body image has been implicated as a major contributor to a number of negative behavioral and psychological problems. Body dissatisfaction is an important contributor to various body-change behaviors ranging from minor weight control methods, such as dieting and increased exercise, to complete restriction of food intake. In fact, body dissatisfaction has emerged as the most consistent contributor to disordered eating. Several other potentially harmful behaviors have also been associated with body image concerns, including use of anabolic steroids and invasive cosmetic surgery. Additionally, body image concerns are strongly related to poor self-esteem, the effects of which can be significantly detrimental to overall well-being.

Prevalence of Body Dissatisfaction

Recent studies have shown that in Western societies such as the United States, as many as 80% of women experience body image dissatisfaction in regard to some aspects of their appearance. It is estimated that over 70% of women and adolescent girls desire a thinner body shape and over 60% report having taken steps toward losing weight. Even preadolescent girls as young as 5 years of age demonstrate body dissatisfaction, with studies showing that about 40–50% of them report a desire to be thinner.

The last two decades have seen a growing awareness that body image concerns are not unique to women and girls. Recent research indicates that around 15–60% of adolescent boys and young men also experience body dissatisfaction. The level of body dissatisfaction among boys and men has often been underestimated, as many studies have only examined body image concerns that are more relevant to women with the focus being on weight and lower body parts. A critical aspect of research with men's and boys' body image is their focus on muscle as well as on weight. Specifically, among adolescent boys, it is estimated that 21–47% have used strategies to increase muscle and/or weight, and 13–48% have used

strategies to lose weight. Studies have also indicated that preadolescent boys demonstrate similar body concerns to adolescent boys and men. Ricciardelli et al. (2006) found that 47% of boys aged 8–11 years desired a thinner body size and 21% desired a larger body size. In addition, close to one-third of boys frequently engaged in weight loss strategies, while almost half of the boys frequently engaged in muscle gain strategies.

Measurement of Body Image

One of the most common methods to measure body dissatisfaction is by using figure rating scales. Figure rating scales consist of a series of human silhouettes, which range from large to small weights, shapes, and sizes. Although different sets are available, they typically consist of figures ranging from very thin to obese. Individuals are instructed to select the figure which they believe best represents their current body size and shape, and then select the figure which they would ideally like to look like. The discrepancy between the two selections reflects the degree of body dissatisfaction. An important feature of figure rating scales is that they have been adapted to suit the target population and also the attribute under inquiry. For instance, there are different versions for women, men, adolescents, and children. Child-versions of figure rating scales are the most common tools for the assessment of body dissatisfaction among children. They are particularly well suited for use with children as the instructions can be easily explained and understood, and they can be completed in a short time. The problem with these rating scales is that although they may demonstrate a difference between the person's ideal and perceived actual body size, they do not indicate how the person feels about this discrepancy (i.e., his or her level of negative affect in relation to the discrepancy). Further, it is difficult with these scales to adequately represent all of the different dimensions of body image (e.g., weight, shape, muscularity).

The measurement of perceptual body image involves assessing the accuracy with which individuals perceive their body size. Contemporary body estimation methods involve the use of computer software that allows participants to manipulate the size of their body and individual body parts to reflect how they perceive themselves. These computer programs have demonstrated excellent psychometric properties; however, the main limitation is that data can be collected from only one participant at a time.

Several questionnaires have also been developed to measure body dissatisfaction. Questionnaires such as the Body Esteem Scale for adolescents and adults (Mendelson et al., 2001) assess dissatisfaction with the body as a whole and tap into how an individual feels about his or her physical appearance and/or body weight. This measure was originally developed for children, and has been validated for children as young as 8 years of age.

Questionnaires that measure the affective component of body image involve the assessment of feelings of anxiety, stress, and shame about specific aspects of the body, or weight and appearance in general. For example, the Body Shame subscale of the Objectified Body Consciousness scale (McKinley and Hyde, 1996) measures feelings of shame as a result of failing to meet culturally defined appearance ideals. Measures focusing on the cognitive dimension assess beliefs, thoughts, and attritions that contribute to body dissatisfaction. The Assessment of Body Image Cognitive Distortions (Jakatdar et al., 2006) is one such questionnaire, which assesses cognitive errors or distortions relating to body image thoughts across different contexts and situations.

Fewer measures have been developed to assess the behavioral component of body image. One self-report measure is the Body Checking Questionnaire (Reas et al., 2002), which assesses body checking behaviors in three domains: overall appearance, specific body parts, and idiosyncratic checking.

In more recent years, several measures have also been designed specifically for men. These include the Male Body Attitudes Scale developed by Tylka et al. (2005), which assesses men's body attitudes across three dimensions: body fat, muscularity, and height. Other measures such as the Drive for Muscularity Scale (McCreary et al., 2004) and the Muscle Appearance Satisfaction Scale (Mayville et al., 2002) provide a more comprehensive assessment of men's concerns with their muscles.

Determinants of Body Image

Psychological models have been fundamental in developing an understanding of body image and its determinants. While several models have been proposed over the last two decades, a common understanding is that body image development is a function of a combination of sociocultural influences and individual factors.

Sociocultural Factors

In Western cultures, a slender figure is considered the ideal for girls and women. The ideal for boys and men is characterized by a muscular yet lean figure, with muscular arms and broad shoulders. Such appearance ideals become influential when they are transmitted and reinforced by sociocultural agents such as the media, family, and peers. The Tripartite Influence Model proposed by Thompson et al. (1999) conceptualizes this relationship by proposing that media, peer, and familial influences predict the development of body dissatisfaction via two mechanisms: internalization of appearance ideals and social comparisons. Internalization refers to the extent to which an individual considers cultural beauty ideals to be important and relevant to him- or herself (Grogan, 2008). Due to the inevitable discrepancy between beauty ideals and one's own appearance, internalization is often associated with body dissatisfaction. Social comparisons are also an important factor in the development of body image concerns. Appearance-related comparisons refer to the process of comparing one's own body and that of another in order to gather information about one's own physical attractiveness (Myers and Crowther, 2009). Studies show that individuals who have a bias toward making appearance-related comparisons are at an increased risk for body dissatisfaction.

The media is frequently recognized as a powerful influence in the development of body image. Research demonstrates

a consistent and vast overrepresentation of idealized thin and muscular bodies in the media. In addition to being underrepresented, overweight characters are commonly portrayed in a negative and stigmatizing manner. Thin characters are usually portrayed as intelligent, happy, attractive, and clean, whereas overweight characters are typically depicted as lazy, self-indulgent, in poor health, lacking self-control, and unattractive. It is therefore unsurprising that body dissatisfaction is associated with exposure to idealized images. For instance, recent *meta*-analyses have demonstrated that media exposure to idealized body shapes is associated with eating disorder symptomatology (Hausenblas et al., 2013). This trend has been found predominantly among women and adolescent girls, but recently, also among men, adolescent boys, and young children. In a review of research on the effects of television and magazines on body image and disordered eating attitudes among women and girls, López-Guimerà et al. (2010) concluded that there is increasing evidence that exposure to media constitutes a direct risk for body dissatisfaction, and also indirectly via peers and parents. The way in which peers and the family reinforce media messages has not been widely researched. However, there is increasing evidence that indicates that the effect of negative messages from a combination of the media, peer, and family greatly increases the risk of body dissatisfaction.

Appearance ideals are conveyed and reinforced by more immediate social agents such as peers. Peers exert their influences on body image via appearance conversations, direct comments, modeling, and social comparisons. For example, appearance conversations with peers involving looks, image, and attractiveness create a social environment where appearance is focused on and valued, thereby reinforcing the importance of the thin/muscular appearance ideals. Lawler and Nixon (2011) found that among Irish adolescents, appearance-related conversations with friends were a predictor of body dissatisfaction and that internalization mediated this relationship. Peers are also an important source of social comparison as perceived similarity is a strong motivating force when choosing a comparison target. A tendency to engage in social comparisons with peers is also an important contributor to body dissatisfaction. This was demonstrated by Halliwell and Harvey (2006) who found that social comparisons were related to body dissatisfaction among both female and male British adolescents aged 11–16 years.

Parents also play an important role in shaping the attitudes and behaviors of their children in regard to weight and appearance. A primary way parents exert this influence is via the modeling of values, feelings, dieting, exercising, and other weight-related behaviors. Research shows that mothers' body dissatisfaction and dieting behaviors are related to their daughters' and sons' body dissatisfaction (van den Berg et al., 2010a). Additionally, parents can directly influence their children's body image by pressuring their children in regard to their weight or appearance, in the form of appearance-related criticism. Parental comments about children's weight, teasing, and encouragement to lose weight have been associated with higher levels of body dissatisfaction among adolescents and children of both genders. For example, Helfert and Warschburger (2011) found that for German adolescents, parental encouragement to control weight and shape was a strong predictor of weight concerns in boys and girls.

Individual Factors

Weight status is the most consistent and robust predictor of body image. The classification of weight status is based upon body mass index (BMI), an index of weight and height; whereby an individual's body mass is divided by the square of his or her height. Studies show that overweight and obese individuals have poorer body image than average-weight individuals, with obese individuals having an even poorer body image than overweight individuals. Furthermore, this relationship has been found to be consistent across gender and age. For example, a 10-year longitudinal study with participants from diverse racial and socioeconomic backgrounds in the United States examined changes in body dissatisfaction from adolescence to young adulthood (Bucchianeri et al., 2013). The researchers found that for males and females, an increase in BMI over time was associated with an increase in body dissatisfaction. Similarly, an Australian study conducted by Olive et al. (2012) with preadolescents aged 7–9 years found that increases in percentage of body fat among girls and boys were associated with greater body dissatisfaction. The relationship between body image and BMI has also been found in other countries, including Spain, Portugal, China, Malaysia, Palestine, and Tonga. For example, McCabe et al. (2012) found that among Tongan adolescents, dissatisfaction with weight and shape was significantly higher among overweight and obese adolescents than among normal-weight adolescents.

The relationship between body image and self-esteem is also well established. Self-esteem is critical for the development of a positive self-image and a sense of self-worth, which are vital in developing a positive body image and promoting general well-being. Childhood and adolescence are particularly significant periods for the development of body image and self-esteem. Several studies have demonstrated the link between the two. For example, in a study conducted with Australian adolescents in grades 7–12, van den Berg et al. (2010b) found that body dissatisfaction and self-esteem were strongly related across different age-groups and for both males and females. These relationships between body dissatisfaction and self-esteem are not only important for young people, but are significant issues throughout the life span. For example, Mellor et al. (2010) examined the relationship between body image and self-esteem across time and age in Australian men and women aged between 20 and 86 years. Self-esteem was related to body dissatisfaction for both men and women, and did not change over a 2-year period or across adulthood. The researchers argued that the finding is unsurprising giving that body image represents a large portion of an individual's self-concept, regardless of gender and age.

Having a perfectionistic personality type is often associated with eating disorders and body image concerns. Perfectionism is characterized by rigid personal expectations, driven by exceedingly high personal standards and critical self-evaluations. Theorists have defined two dimensions underlying the concept of perfectionism, which have been described

as maladaptive and adaptive perfectionisms. Adaptive perfectionism is related to high achievement standards and is generally not associated with psychological distress, whereas maladaptive perfectionism is related to negative reinforcement and self-defeating behaviors (Slade and Owens, 1998). Maladaptive perfectionism has been shown to be related to a number of negative health outcomes, including anxiety and depression, and is an important factor in the development and maintenance of body concerns and eating pathology. Although adaptive perfectionism is thought to be less problematic, body dissatisfaction may be one context where adaptive perfectionism may also be detrimental, as some studies have found that both adaptive and maladaptive perfectionisms are associated with body dissatisfaction. For example, Wade and Tiggemann (2013) found that both adaptive and maladaptive perfectionisms were associated with body dissatisfaction among women aged 28–40 years.

Body Image across Gender and the Life Span

Childhood is a significant time for social and cognitive development. A number of different aspects of children's socialization have implications for their body image development. Social comparisons are a fundamental aspect of children's cognitive, social, and emotional developments. Children learn about their own abilities, differences, strengths, and weaknesses via social comparisons. Around the age of 7–8 years, children's social comparisons become increasingly evaluative and more frequently used. This is also a significant age for the development of body dissatisfaction. Holt and Ricciardelli (2002) found that 30% of boys and girls engaged in social comparisons in regard to aspects of their body, including their weight and muscles. These comparisons were related to problem in eating attitudes, lower levels of self-esteem, and higher levels of negative affect.

For both adolescent and preadolescent boys, performance in sport is closely related to their self-esteem and body image. Sport plays an important socializing role for boys, but it is also a way for boys to develop and demonstrate their muscularity. Sport also provides a context for boys to more openly discuss what they like and do not like about their bodies, and many aspects of the body that boys want to improve are those that would make them more successful at sport. These include a focus on strength, endurance, and toughness. Thus, whereas girls focus on their appearance, body image for boys is primarily focused on the function of their bodies. Even in qualitative interviews with boys aged 5 and 6 years, Birbeck and Drummond (2006) found that boys associated a larger body with greater physical performance. Boys maintained that if one was 'bigger,' one could run faster, play football better, and have other physical advantages.

One of the most critical milestones for individuals is puberty. For girls and boys, puberty is accompanied by major changes in their body, their self-concept, mood, and social interactions. There are important differences for girls and boys during this time. Boys often have a positive pubertal experience as developmental changes, which include increases in stature and muscle, move them closer toward achieving the ideal male body shape. On the other hand, girls often find that physical changes that accompany puberty, for example, weight gain, move them further away from beauty ideals for women. For girls and boys, early or late onset of puberty can lead to feelings of alienation and depression. In particular, for girls, research has shown that pubertal development predicts body dissatisfaction, whereas for boys the relationship appears to be less consistent. In one study, McCabe and Ricciardelli (2004) found that early pubertal onset was a risk factor for body dissatisfaction in girls, whereas early maturing boys demonstrated higher levels of body satisfaction. Despite these higher levels of body satisfaction, early maturing boys were more likely to adopt strategies to decrease weight and increase muscle, perhaps because of their focus on achievement in sport.

Pregnancy is another significant change which impacts on adult women's body image. Women often report that they are satisfied with their bodies during pregnancy, and in some cases research has demonstrated that pregnant women are actually happier with their bodies than they were prior to being pregnant. It is thought that this is due to women's greater acceptance of bodily changes as a reflection of the healthy development of the growing baby. For example, Clark et al. (2009) found that during pregnancy, women's perceived attractiveness remained stable, whereas women reported greater body dissatisfaction after the baby was born.

Studies have shown that women in their 40s and 50s are as likely to desire a thinner figure or engage in weight loss strategies as are women in their 20s. Appearance ideals are often at odds with natural changes that occur in a woman's body with age. For example, women experience pressure associated with maintaining a youthful appearance. In efforts to keep faces and bodies smooth, taut, slim, and wrinkle-free, women are increasingly turning toward invasive cosmetic procedures such as face lifts and collagen treatments. One developmental factor significant for this age-group is the onset of menopause. Studies have shown that the changes which often accompany menopause are associated with increased body dissatisfaction. This is often related to weight gain, which is a common characteristic of menopause. The progression into older adulthood is accompanied by major physical changes including wrinkling of the skin, loss of muscle, graying of the hair, and loss of height. In a study of body image among American women aged 25–89 years, Runfola et al. (2013) found that body dissatisfaction significantly decreased across older aged women; however, the association was no longer significant after stratifying for BMI. In addition, other studies have shown that over 60% of women aged between 60 and 85 years report being dissatisfied with their body weight and/or appearance.

There is little research currently available that has examined the development of body image during adulthood for men. Some studies show that older men display more body dissatisfaction than younger adult men, while other studies show no age-related trends. Studies which have examined body image among older men are rare; however, one study conducted by Peat et al. (2011) found significant differences in body dissatisfaction between younger and older men, and found that younger men demonstrated greater dissatisfaction despite having a lower BMI. A similar finding was obtained by McCabe and McGreevy (2011). The researchers argue that this finding may reflect differential media pressures on younger

and older males, with media influences becoming less relevant for older men.

Body Image in Different Cultural Groups

The study of body image across cultures is also important given there are cultural differences that can give rise to diverse beauty ideals and body modification practices. These have been studied both within different cultural groups in Western countries, and between Western and non-Western countries.

Black American women are one cultural group who have been found to report low levels of body dissatisfaction. Black women in the United States tend to have larger body sizes; yet relative to White women, they are often found to be more satisfied with their bodies. In a *meta*-analysis of 98 studies conducted between 1960 and 2004, Black women were found to consistently report less body dissatisfaction than White or Hispanic women (Kronenfeld et al., 2010). Body ideal differences are often attributed to differences in BMI. For instance, Blacks in the United States are much more likely to be obese or overweight than Whites. However, family and peers are viewed as providing protective barriers against cultural messages, which reinforce the thin ideal. Granberg et al. (2009) found that greater positive appearance-related feedback from family and peers was associated with being more comfortable with a larger body shape.

In Hispanic communities, there may also be more acceptance of a wider range of body types than found among Whites. For Hispanic women, the ideal figure is represented as curvaceously slender with fat distributed in specific areas such as the breasts, buttock, and hips. However, research comparing the rate of body dissatisfaction between Hispanics and Whites has provided mixed findings. Some studies indicate that Hispanic girls and women experience greater body satisfaction and less concern with weight compared to White girls and women. Other studies have found that Hispanic girls and women are as dissatisfied as White girls and women. Hispanic males' body image does not seem to differ from White males' body image, as the majority of studies have found no differences between Hispanics and Whites (Ricciardelli et al., 2007).

In stark contrast to Western appearance ideals, which are defined by thinness, non-Western cultures have traditionally valued and striven toward achieving a larger body shape. Research suggests that ideal body shapes are slimmer in countries with higher socioeconomic status, such as Westernized societies. In less socioeconomically developed countries, a larger body shape is more desirable as it signifies personal wealth, social status, fertility, and sexuality among women. This may provide some understanding to findings of cross-cultural differences such as those found by McCabe et al. (2012) who examined body dissatisfaction across eight different countries. The researchers found that Fijian and Tongan men and women were among the highest for body size status, yet also expressed the highest level of body satisfaction. The nature of the messages that are received regarding the value of a large body size is important in shaping the body image idea and hence the levels of body dissatisfaction. In these countries, a large body is a sign of status, care, and respect. Researchers have highlighted the effects of globalization and the spread of Westernized media imagery as a major reason why even in developing nations, body image concerns and the desire for thinness are becoming increasingly prevalent.

Preventing Body Image Concerns

School-based intervention programs are increasingly being adopted as a means of preventing and reducing body image concerns and eating problems among children and adolescents. There have been different approaches to addressing body image within the classroom. Self-esteem approaches have found some success by drawing upon Social Cognitive Theory in order to tap into students' self-beliefs and attitudes associated with their body image. The 'Everybody is Different' program adopted this approach with Australian adolescents in grades 7 and 8. With a specific focus on the development of self-esteem and positive self-image, this 9-week program demonstrated improvements in body image for both girls and boys, immediately post program and also at 12-months follow-up. Media literacy approaches have also become a common way to address the negative influence of the media via the education of students to understand the ways in which media images create social norms. This involves critically analyzing media images, and recognizing the portrayal of stereotypes, to discover how media images are 'perfected' with the use of airbrushing and retouching. Recently, increasing awareness of body image concerns among preadolescent and adolescent boys has led to the development of school-based body image programs specifically for boys. Stanford and McCabe (2005) developed a program aimed to enhance adolescent boys' self-identity and self-esteem, promote acceptance of different body shapes, and develop media literacy. The program resulted in increased self-esteem and satisfaction with muscles, and reduced negative affect, particularly among those boys who already experienced high levels of body dissatisfaction.

In addressing the various influences that impact on children's and adolescents' body image, prevention efforts need to target the broader school environment, well beyond the confines of the classroom. A whole-school approach involves the collective effort of the school and community to promote health and positive self-image. Policies such as antibullying and greater tolerance of individual differences have potential for the most wide-reaching and powerful effects.

At the public policy level, initiatives have also been developed by a number of governments in efforts to address body image concerns and problem eating. In some countries, government legislation has been developed to reduce exposure, internalization, or pressure associated with thin ideals. For example, the Spanish Government has banned the broadcasting of television commercials that promote beauty products, cosmetic surgery, and chemical options for achieving an ideal appearance. Several other countries, which include Australia, Italy, France, and Canada, have also developed codes of conduct for media and related industries. These generally aim to influence the presentation of media images in a way that is less likely to contribute to the development of body image concerns and problem eating. For example, in Australia, the Federal Government has promoted voluntary media and industry codes of conduct in which media and fashion

organizations are encouraged to not digitally manipulate images and to represent a diverse range of body shapes.

Conclusion

The concept of body image has had a long history of development over the last century. It is shaped by biological, psychological, and sociocultural factors. These include the spread of Western media, as portrayed in magazines, television, and films. Body image is strongly associated with psychological adjustment, as well as health risk behaviors related to eating and building muscles. Current research demonstrates that body image and body image concerns are no longer topics that are exclusively relevant to women and adolescent girls, but rather they are of relevance to males and females, regardless of age or cultural background. Prevention and intervention programs to address these body image concerns need to be designed so that they address the specific concerns of the target group.

Bologna Process

Abstract

This article describes the Bologna Process in higher education in Europe that started with the Bologna Declaration signed by 29 Ministers of Education of different European countries in 1999, and aimed to create the European Higher Education Area. Based on cooperation between ministries, higher education institutions, students and academic staff, this initiative grew to encompass 47 countries and various international organizations by 2012. This article describes the European institutions involved and analyzes the effects of the Bologna Process on social work education and practice to highlight strengths and weaknesses in this approach.

Introduction

Education plays an important role in integration processes aimed at developing a common identity in a subcontinent composed of different nation-states with their own histories, cultures, policies, and traditions. The concept of identity is a slippery one, including the European identity in relation to social work (Frost, 2008). Formal European agencies were involved in creating the Bologna framework. Crucial among these is the Council of Europe, established under the 1949 London Treaty to promote democracy, protect human rights, and enforce the rule of law in Europe among the 47 countries that form this organization. During this period, different agencies created to preserve peace in Europe had the political and economic aims of strengthening integration between member countries. In 1958 they established the European Economic Community (EEC). Since then, a huge single market has been created and continues to develop its full potential as what began as a purely economic union evolves into an organization that spans all policy areas including development aid and the environment. The Maastricht Treaty signed on 7 February 1992 was enacted on 1 November 1993 when the EEC changed its name to the European Union (EU) that currently has 27 member states. The Bologna Process was a European intervention in higher education. I consider its role in devising a more unified identity for social work below.

There was an aspiration for closer cooperation between member states at all levels of education since the first Education Action Program in 1976. In the1980s, with the emergence of 'social Europe,' the European Commission (a body representing the interests of the EU as a whole) proposed new legislation to the European Parliament with the key objectives of developing and improving the European component within teaching; and promoting geographical mobility among students. Two measures, the Socrates and Erasmus Mobility Programs, have had significant impact upon the creation of a European identity and development of better understandings of many common problems that affect European societies (Campanini, 2007). These have encouraged the evolution of a social work shared knowledge base and identified a need to strengthen the intercultural dimension within student learning, and prepare younger generations for life in societies increasingly characterized by cultural and linguistic diversities where capacity to fight racism and xenophobia is important. Social work educators participated actively in many such initiatives including: the Tempus Programme that supported the development of social work education in Eastern European countries; and Thematic Network Scheme (ECSPRESS, led by Walter Lorenz from 1996 to1999, examined the social professions in Europe; EUSW, coordinated by Annamaria Campanini, from 2002 to 2008 followed the Bologna Process).

What Is the Bologna Process?

The Bologna Process is a route aimed at creating the European Higher Education Area (EHEA) through cooperation between ministries, higher education institutions, students, and staff from 47 countries, with the participation of international organizations. The name comes from the first Declaration signed in Bologna (Italy) on 19 June 1999 by ministers in charge of higher education from 29 European countries. The idea had emerged in 1998, during the celebration of the 800th anniversary of the University of Paris when education ministers from France, Germany, the United Kingdom, and Italy decided that the segmentation of the higher education sector in Europe was outdated and harmful. To counteract this, they signed the Sorbonne Joint Declaration to create a common frame of reference within the intended EHEA to promote student, teaching staff, and graduate mobility and develop qualifications suited to the labor market.

This voluntary process, initiated with the Bologna Declaration (1999), was to harmonize diverse European Higher Education Systems by 2010 through a European Space of Higher Education.

Bologna's specific aims were to increase the employment prospects and geographical mobility of European citizens; and enhance the reputation of European Higher Education globally. To realize this project it was necessary to plan long-term actions that would achieve:

- Easily, comprehensible and comparable systems of degrees.
- An educational structure founded upon two cycles (BA and MA), using the European Credits Transfer System.
- Geographical mobility for students, teachers, researchers, and administrative staff, and recognition of experiences within a European context.
- European cooperation in quality assurance and the development of comparable criteria and methodologies.

These established the first steps of the Bologna Process. During subsequent biannual Ministerial Conferences this educational agenda was broadened through further communiqués. Increasing intercountry participation (47 out of the 49 countries that ratified the European Cultural Convention of the Council of Europe in 1954 are now involved) resulted in further evolution of the main objectives and tools. Each meeting produced further steps down the harmonization path and highlighted different aspects of the new higher education policy. While acknowledging the strengths of this process, dissenting voices were expressed in the Nordic countries and Portugal by educators concerned about the dilution of standards (Dominelli, 2007).

The Prague Communiqué in 2001 had 33 member states expanding these objectives by stressing the importance of lifelong learning as an essential strategy within the EHEA. Additionally, students were configured as active partners in enhancing the attractiveness and competitiveness of European Higher Education. Other important dimensions were the introduction of the 'social' dimension expressed as equality of opportunities in higher education; facing the challenges of competitiveness and new technologies; and improving social cohesion, equal opportunities for all citizens, and quality of life. Participating ministers committed to ensuring the further development of quality assurance mechanisms and national qualification frameworks.

The Berlin Communiqué, enlarging the number of countries to 40 members, was adopted in 2003 and emphasized research, research training, and interdisciplinarity, in maintaining and enhancing the attractiveness of higher education in Europe. Another aspect it highlighted was that of developing an agreed set of standards, procedures, and guidelines on quality assurance to secure implementation of an adequate peer review system. Connected with the topic of comparability, the communiqué invited member states to develop a framework of comparable and compatible qualifications for their higher education systems, which would describe qualifications in terms of workload, level, learning outcomes, competences, and profile. The different levels of degree were to have different orientations and profiles, to accommodate a diversity of individual, academic, and labor market needs.

These Communiqués, predicated on the Lisbon Recognition Convention (1998), argued that first cycle degrees (Bachelors) should provide access to the second cycle programs (Masters), which would lead to doctoral studies. The Berlin Communiqué (2003) recommends the introduction of a universal 'diploma supplement' (transcript with description of the types of institution and level of the degree) to be annexed to each certificate by 2005. This was to facilitate recognition of titles across all European countries, in accordance with the Lisbon Convention (1998).

The Bergen Communiqué of 2005 emphasized the significance of higher education in enhancing research; underpinning higher education; bringing economic and cultural development within European societies; and promoting social cohesion. It also asserted that efforts to introduce structural change and improve the quality of teaching should not detract from efforts to strengthen research and innovation. And, it emphasized the centrality of partnerships among diverse stakeholders – students, HEIs, academic staff, and employers. Regarding the third cycle (doctoral studies), ministers highlighted the need for doctoral level qualifications to be fully aligned within the overarching EHEA framework for qualifications using the outcomes-based approach. Participants in doctoral programs were to be deemed both students and early stage researchers that advanced knowledge through original research. The document emphasized the need to increase the number of doctoral candidates and doctoral programs that promoted interdisciplinary training, developed transferable skills, and guaranteed transparent supervision and assessment.

In 2007, the London Communiqué engaged 46 countries and evaluated achievements in mobility, degree structure, recognition, qualification frameworks (both overarching and national), lifelong learning, quality assurance, and the 'social' dimension alongside the economic one. The inclusion of the 'social' was very important for social work as it is embedded within this domain. An increasing awareness that a significant outcome of the process would be a move toward student-centered higher education and away from teacher-driven provision became evident. This meeting also set priorities for 2009: mobility and the 'social' dimension, which were defined for the first time, data collection, employability, EHEA in a global context, and stock taking. For 2010 and beyond, it stressed further collaboration and an opportunity to reformulate the visions and values of this important process.

The last meeting, before the official end of the first phase of the Bologna Process was held in Leuven/Louvain-la-Neuve in 2009. It aimed to define the working areas for the next decade – to enhance the Bologna Process through an in-depth realization of the reforms. Emphasis was on the 'social' dimension, lifelong learning, employability, student-centered learning, the teaching mission of education, international openness, mobility, education, research and innovation, data collection of the implementation of the Bologna Process among participating countries, funding of the HE, and multidimensional transparency tools.

The Impact of the Bologna Process on Social Work Education

In March 2010, in Budapest–Vienna, a decade of the Bologna Process was celebrated with an Anniversary Conference, for the official launching of the EHEA. The Bologna Process has given social work an incredible opportunity to engage with educational systems across Europe. As Lorenz (2006) and Lyons and Lawrence (2006) among others claim, social work is strictly related to specific cultural and contextual dimensions of the different countries in which it is operating. Historical backgrounds, social policy trends, pedagogical and disciplinary relationships, and 'politics' all have implications for the way in which training in social work has been established in different countries and for the specific features in which social work roles have been interpreted. Local factors and European policy developments are significant elements in determining how social work education evolves its structures, curricula, and pedagogical issues and the roles that social workers will play in the social scene. In the book, *European Social Work. Commonalities and Differences* (Campanini and Frost, 2004) representatives of 24 different European nations presented the 'state of

the art' of social work in their countries, giving a clear image of commonalities and differences in social work education at different levels. Other research, e.g., by Martinez (2007) and Hamburger et al. (2004–2007), focused specifically on social education in the wake of the Bologna Process and structures across Europe and on fieldwork education/placements in 15 European countries (Campanini, 2009). These studies reveal that despite the Bologna Process, which aimed to harmonize higher education in Europe, meaningful differences between countries persist, including variety in educational providers and manner of delivery (Campanini, 2011).

Alongside countries that have recently entrusted social work education to the university sector are those that have developed learning routes in higher private or public institutes. Nations such as Poland, Lithuania, and Portugal have the simultaneous presence of various educational contexts, e.g., public and private universities and colleges, in others, employing agencies are at the fore as in the work-based route in the United Kingdom. The Bologna Process has also recognized institutions like Fachhochschule (Germany) or Hogeschoolen (Netherlands, Denmark) as universities of applied or professional sciences with the power to organize BAs. However, the second education level (Masters) remains the prerogative of universities that retain sole responsibility for providing the third level (doctoral studies).

Despite many changes that have already taken place, the need to restructure educational paths in accordance with the Bologna Process of 180 credits for the first cycle of 3 years (the BA) and 120 credits for the second cycle (MA), or alternatively 240 credits for 4 years for the BA, and 60 credits for 1 year for the MA remains, while differences have not always been successfully harmonized and first and second cycles can be of varying lengths. The Bologna Process stipulates 300 credits and 5 years of study for a Master's degree, but countries have responded differently, e.g., Sweden, has settled on 3.5 years plus 1.5 years pattern, while Spain defined its curriculum as 4 years plus 1, and Italy 3 years plus 2.

There are also differences in the disciplinary components of the curricula and internship (practice placement) organization. The foundational base of social work education includes disciplines like the human and social sciences of sociology, psychology, social pedagogy, social policy, and legal studies. Curricula vary in the subjects offered and prepare students to undertake distinct roles, thereby contributing to professional differentiation. Additionally, preparation for professional practice – variously referred to as 'placement,' 'fieldwork,' or 'practice education,' – differs in the number of hours dedicated to social work theory and supervised practice and the modalities within which the training is conducted. These can vary from 50% of the entire period of study as in the United Kingdom, to 210 h in Estonia.

Teaching methodologies also vary. The Bologna Process places the student as the central actor in the learning process. However, the role of teachers on social work courses can be quite different and is determined by the 'learning process' that dominates a particular national context. Active learning has a very strong background and presence in Scandinavian countries, with specific tools and evaluation processes more oriented to helping the student develop a critical and self-reflective attitude (Campanini et al., 2012; Frost et al., 2012). In contrast, in Italy, e.g., more conventional methods based on the traditional notion of an expert lecturer imparting knowledge to educable and eager students are used. The EU has funded web-based courses since the late 1990s (Dominelli and Thomas Bernard, 2003), but Information and Communications Technologies (ICTs) technologies are only slowly entering social work education. As an example, the Norwegian-led initiative of a virtual classroom, 'Virclass' involving teachers and students from different countries, has proved useful for organizing pan-European modules (Larsen and Hole, 2007; viewable on www.virclass.net).

As foreseen by the Berlin communiqué, research is a pillar of the knowledge society and important for enhancing social work education (Campanini, 2007). The inclusion of research within education varies considerably among countries. Nations such as Sweden and the United Kingdom have a long tradition of PhD studies linked to extensive publication of social work research. In Finland, the creation of a joint venture between the universities through SOSNET allowed intensive cooperation in research including conducting several research projects concerned with questions about social work education, expertise, and practical training. Many countries are now organizing PhD programs specifically in social work or as a pathway within other disciplines. For example, in 2013, France added a title of 'social work' in sociology and pedagogy PhD courses. There are still problems linked with the positioning of social work education inside and outside the university, both in relation to having students undertake research degrees, and the expectation that teachers will be research active (Lyons, 2006). Yet, more and more social work teachers are required to have a PhD and be evaluated in relation to research, as occurs regularly in the United Kingdom.

Involvement and participation in European projects and activities is high in nearly all countries and social work has been active in opening itself to comparisons in social work education in various ways on an inter-European level (Campanini and Frost, 2004; Lyons and Lawrence, 2006; Friesenhan et al., 2012) and with North America since the late 1990s; and more recently to Asian-Pacific countries. Educators in many countries use the opportunities made available by the European Community for student mobility and teaching staff exchanges (Dominelli and Bernard, 2003).

These can involve intensive periods of study on specific topics through concentrated programs and particular initiatives that are open to contributions from teachers of various nations including during an international week. Opening education to a wider vision is also demonstrated by the insertion of modules that address various comparative aspects into social work while offering experiences through summer schools, e.g., Fachhochschule Alice Salomon in Berlin, Rovaniemi University of Applied Science in Finland, and those held in Parma (Italy) and Dornbirn (Austria) by the European Social Work Thematic Network (EUSW-TN). Some offer international Master's courses: e.g., Master of Arts in Comparative European Studies (MACESS) in Maastricht; Goteborg University; and Instituto Superior de Ciencias do Trabalho de Emrpesa (ISCTE) Lisbon. Others attempt to create specific courses that award the title of 'Bachelor of Intercultural and International Social Work' as in Copenhagen. In spite of these initiatives, difficulties remain. These include students and staff having insufficient knowledge

of languages, especially in France, Great Britain, Italy, and Spain; problems related to different scheduling and timetabling of courses; and the economic costs of studying abroad. These can all limit student mobility (Dominelli and Bernard, 2003). Reluctance to operate transnationally might be indicative of an inward facing attitude, whereby the European dimensions of engagement are not perceived as opportunities. Students then fail to develop intercultural and international professional competences that are now seen as core competencies in many parts of Europe.

The Bologna Process gave quality assurance considerable importance. 'The European Network for Quality Assurance in Higher Education (ENQA)' was established in 2000 to promote European cooperation in the field of quality assurance. In November 2004, the General Assembly of this network renamed the ENQA. The idea of the Association originated from the European Pilot Project for Evaluating Quality in Higher Education (1994–95) that demonstrated the value of sharing and developing experience in the area of quality assurance.

The Bologna Process has developed a substantial number of exchanges, contacts, and reflections. However, more remain to be done to harmonize social work education and balance the sharing of commonalities while respecting the particularities and differences of specific local contexts.

Bologna Process: A New Phase

A new phase of consolidation and operationalization among European countries has led to the formation of closer links with higher education systems around the world, including an increasing number of non-EU countries becoming involved in dialogue with countries participating in the Bologna Process to enhance worldwide cooperation in higher education. In 2009, a Bologna Policy Forum was organized in Leuven/Louvain-la-Neuve between Ministers of the 46 Bologna countries and colleagues from different parts of the world, and a wide range of NGOs to facilitate global dialogue for the first time. This event focused on the key role that HE plays in the development of society, based on lifelong learning and equitable access to learning opportunities at all levels of society; and importance of public investment in higher education. In spite of the economic crisis, transnational exchanges in higher education governed by academic values, a balanced exchange of teachers, researchers, and students between countries continue to promote fair and fruitful 'brain circulation,' as an alternative to the 'brain drain.' This ministerial initiative has become a regular event at the EHEA Ministerial Conferences.

In the second Bologna Policy Forum in Vienna, in March 2010, a specific Statement was adopted referring to the manner in which higher education systems and institutions responded to growing demand for their services, multiple expectations, and the balance between cooperation and competition in international higher education. This Forum's Statement included concrete feedback to be adopted by participants, e.g., nominating contact persons for each participating country to act as liaison points for the better flow of information and joint activities, and support global student dialogue.

The overarching theme of the third Bologna Policy Forum held in Bucharest in April 2012 was "Beyond the Bologna Process: Creating and connecting national, regional and global higher education spaces." It emphasized four topics: public responsibility for higher education within national and regional contexts; global academic mobility; incentives, barriers, balances, and imbalances in global and regional approaches to quality enhancement in higher education; and the contribution of HE reforms in enhancing graduate employability.

The Bologna Process is ongoing. The Leuven Communiqué adopted during the first Bologna Policy Forum established 10 priorities for the decade to 2019 to ensure more comparable, compatible, and coherent systems of higher education in Europe. These were the social dimension; lifelong learning; employability; student-centered learning; education, research, and innovation; international openness; mobility; data collection; multidimensional transparency tools; and funding. Some working groups and networks like the EHEA Information and Promotion Network; Network for Experts in Student Support in Europe; Network for National Qualifications Frameworks Correspondents were formed to monitor progress and report on the implementation of the Bologna Process. After the launching of the EHEA, the Bologna Process moved toward a new phase, a more in-depth one aimed at reducing discrepancies in the countries forming the EHEA. To support these efforts with joint action at European level, the ministers entrusted the Bologna Follow-up Group to prepare a work plan for the period 2012–15.

During the third Bologna Policy Forum in Bucharest in April 2012, the Ministerial Conference underlined the importance of higher education reform to generate sustainable growth and jobs in the face of the economic crisis. Its three key aims were to provide quality higher education to more students; better equip students with employable skills; and increase student mobility. A strategy was formulated to increase mobility with the specific target that at least 20% of those graduating in Europe in 2020 would have been on a study or training period abroad. This last requirement is very important in social work education, given its local base in practice. Having students study in a foreign country can encourage and test their ability in languages other than their mother tongue, capacity to understand a new reality, become more culturally aware, and recognize commonalities and differences in each situation. It also speeds up the abandonment of rigid premises, preconstituted certainties, and stereotypes; helps to understand the links between the theoretical frames of reference and concrete actions; engage with opportunities and constraints in social policies and the choices of social services organization (Dominelli and Thomas Bernard, 2003; Payne and Askeland, 2008; Campanini, 2009).

The Effects of the Bologna Process: From Education to Practice

Despite many initiatives aimed at exploring social work education in different countries undertaken through the activities of the EUSW Thematic Network, teacher exchanges, participation in other measures through the Erasmus–Socrates framework, and seminars and conferences organized by the European Association of Schools of Social Work, it has been impossible to detail and agree a comprehensive description of

core competences for the social work profession thus far. There are many reasons for this. The principal one is related to diverse conceptions of the social work profession in different European countries. To tackle this problem, more time and money would have to be invested in meetings, including the formation of a new Thematic Network on this topic, if the European Commission would have funded it. Unfortunately, neither a dissemination project nor a new proposal for a Thematic Network was accepted.

Nonetheless, the Bologna Process remains an important framework for drawing up general guidelines and providing specific tools to support this process. For example, an important aspect within the harmonization process is the definition of the 'Dublin descriptors'; the product of an informal group of specialists originating from different countries, who participated in the 'The Joint Quality Initiative network.' These descriptors clarified what is expected from students – knowledge and understanding, application of this knowledge and understanding, making judgments, communication skills, and learning skills. These specific qualities are adapted and matched to the demands of the perceived successful completion of the first, second, and third Bologna cycles, and highlight progression between these cycles (www.jointquality.org).

Another interesting initiative in the harmonization process is the project 'Tuning Educational Structures in Europe,' submitted to the European Commission at the end of 2000. It is still working toward an overall objective of implementing discussion and reflection upon the changes that Bologna has brought to educational structures and study content. The process of reforming requires a 'tuning' of curricula, in terms of structures, programs, and teaching. Although it is very important to protect the rich diversity within European education, it is also necessary to identify competences, learning outcomes, and design, and construct and assess the qualifications provided through this education (www.unideusto.org/tuning/).

The final reports by González and Wagenaar (2003), and González and Wagenaar (2005), from the 'Tuning' project, contain guidelines and practical examples. A specific group ran with the ambition to link the Dublin descriptors of the European Qualification Framework (EQF) for the EHEA with the eight levels of the EQF for Lifelong Learning in the Social Sciences. Operating during the period 2008–10, representatives of social work education participated in this group alongside colleagues from psychology, education, and occupational therapy.

The final document published on the 'Tuning' Web site has remained more a 'cultural' exercise than a starting point that identifies and discusses concrete applications for social work as has occurred for nurses or occupational therapists. As explored by Lyons and Lawrence (2006), the past two decades have witnessed significant changes, not only in the construction of Europe, but also within education in the social professions including social work, but with different consequences. Although the Bologna Process provides a strategic opportunity to augment professional growth and progress within social work, Juliusdottir (2006) argues that a reflexive process of becoming more academic creates conditions for a dialogue to emerge between social work and academic cultures that could lead to interdisciplinary understanding and mutual respect. Being a part of this culture facilitates fresh motivations for training and active participation in social workers' own knowledge production through research and other theoretical activities, raising social workers' confidence and status in society. And, it may lead to increased compatibility and mobility associated with increasing globalization and shared labor markets. Christine Labonté (2005) emphasizes the possibility, of retaining a generic program at Bachelor's level, then providing a greater degree of specialization, required particularly for the new professional fields, by offering specially tailored Masters programs as a by-product of a tiered academic structure. Dominelli (2007) argues that this also facilitates the linking of a ladder of qualifications to career structures whereby lecturers and managers hold doctorates, although transitional arrangements may be needed in some countries. The 'advanced' study program can be conceptualized as part of specific 'skilling' or reskilling and lifelong learning. However, a simultaneous disadvantage of the two cycles structure is "the danger of reducing the professional element of training, by subjecting it to purely academic quality criteria, and what is more, academic criteria that are largely not defined from within an 'indigenous' discipline" (Lorenz, 2006: p. 54).

Other problems arise from differing levels of importance accorded to the BA and MA in different countries; connected to the historical and cultural context of education in each country. One trend promotes the awarding of the social work qualification after an overall 5-year academic package, whereas another views the MA as an area for specialization, often connected with 'advanced' (e.g., managerial) tasks. The Bologna Process introduced vibrant discussions on the changes needed to revise the educational systems to meet its demands and implement it, as occurred in Portugal, where the social work qualification was achieved in 5 years or in Spain that was going in the same direction. Paradoxically, in Italy, where the document was first signed, the aims were only met at a structural level. Its philosophical premises and the two different levels recognized in the Professional Register were not given the same recognition in the labor market (Campanini, 2009).

From a connected but different point, Walliman (2004) emphasizes the dangers of an educational structure too exclusively responsive to, and tied up with market needs. He links this without and out competition between education providers, which might lead to a process of privatization within education, analogous to outcomes driven by the General Agreement on Trade in Services. This could create university programs for elites with higher costs and fewer opportunities of equal access for everyone.

The Bologna Process has motivated academics to reflect upon and discuss topics connected with both the problems and opportunities created by the new structures within social work education, and contemporary challenges regarding teaching methods and new identities for students in social work. In this context, the effort to intensify cross-national analytical comparisons is oriented toward clarifying current situations; and stepping back from daily activities to "regain a degree of initiative and autonomy and develop quality criteria that are accountable to the users of social services" (Lorenz, 2006: p. 57).

I conclude that the Bologna Process has given an important input to developing a strong interest in participating in mutually identifying processes that recognize common

concerns alongside ethical principles and promoting a European social work identity. According to Frost (2008: p. 350):

> Examples of social work constituencies in European countries forging links and associations, projects and cooperative activities to engender European social work identities are burgeoning, with the EU itself financing some of this work. In social work education and academia particularly, there is perceptible evidence of conscious attempts to develop Europeanization.

Another important consideration is whether social work in Europe educates for 'Bologna competences' as well as national expectations. 'European' social workers must be educated to meet the general Bologna competencies, but importantly in every country, education is expected to equip students to fulfill fundamental social work values around situating understanding and interventions in their specific cultural and ethnic contexts (Campanini and Frost, 2004).

Abstract

This article provides a brief introduction to the life and work of Luc Boltanski, who is widely regarded as one of the most influential French sociologists of the late twentieth and early twenty-first centuries. The article is divided into two main parts. The first part offers a summary of Boltanski's biographical trajectory and academic career. The second part gives a comprehensive overview of Boltanski's major works and intellectual contributions. The concluding section presents a short assessment of Boltanski's overall impact upon the contemporary social sciences, particularly in terms of the international relevance of his writings. The bibliography contains *key* primary and secondary sources, reflecting not only the prolific development of Boltanski's oeuvre, but also the strong influence his work has had, and continues to have, on cutting-edge forms of social and political analysis.

Biographical Facts

Luc Boltanski is widely regarded as one of the most influential French sociologists of the late twentieth and early twenty-first centuries. He is one of the leading figures of the 'pragmatic' tradition within contemporary social and political thought. More specifically, he – along with Laurent Thévenot – is one of the founding figures of an approach that he himself characterizes as the 'pragmatic sociology of critique.'

Boltanski was born in 1940. He studied social sciences at the University of Paris, La Sorbonne, and completed his *Thèse de troisième cycle* in 1968. This dissertation – entitled *Prime éducation et morale de classe* – was supervised by Raymond Aron; it was published in 1969 and subsequently translated into Italian and Spanish. Boltanski was awarded a *Doctorat d'État* in 1981 for his thesis entitled *Les cadres. La formation d'un groupe social*; this study, completed under the supervision of Pierre Ansart, was published in 1982.

Throughout his career Boltanski has been based at the *École des Hautes Études en Sciences Sociales* (EHESS), Paris, France. At the EHESS, he has held three major academic positions: *Chef de travaux* (1965–69), *Maître de conférences* (1970–81), and *Directeur d'études* (since 1982).

Between 1965 and 1984, he was a member of the *Centre de Sociologie Européenne* (EHESS/CNRS), directed by Pierre Bourdieu. In 1985, he – together with Laurent Thévenot – co-founded the *Groupe de Sociologie Politique et Morale* (GSPM, EHESS/CNRS), of which he was the director between 1985 and 1992. At the GSPM, he carried out several research projects and led numerous research programs until its closure in 2013. He has been a Visiting Professor at various universities, both in Europe and in the United States, and he was a member of the Institute for Advanced Study at Princeton University during the academic year 1991–92. Currently, he is a member of the *Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux (Sciences Sociales, Politique, Santé)* (IRIS, EHESS).

In the early 1970s, Boltanski was involved in launching the journal *Actes de la recherche en sciences sociales*, when his research was still profoundly influenced by the works of his academic mentor, Pierre Bourdieu. In the mid-1980s, however, Boltanski dissociated himself from Bourdieu's 'critical sociology,' in order to create his own research program, commonly described as the 'sociology of critique' or, more recently, as the 'pragmatic sociology of critique.'

Between 1965 and 1982, Boltanski's key research interests were directed toward the sociology of social classes and social stratification (mainly within the following areas: bodily and medical practices, education, social classifications, and moral norms). Between 1983 and 2009, his sociological investigations were concerned, primarily, with two areas of interest: first, *different notions of justice*, particularly in relation to disputes and critique; and, second, *transformations of capitalism*, especially those taking place between the early 1960s and the late 1990s. In relation to these research foci, Boltanski has sought to develop a 'sociology of critique,' based on empirical fieldwork undertaken in a number of domains, such as the media, state policies, management, as well as new forms of work and organization.

In 2008, Boltanski delivered the Adorno Lectures at Frankfurt, which were subsequently published as *De la critique. Précis de sociologie de l'émancipation* (Paris: Gallimard, 2009). In 2012, he was awarded the *Lauréat du 1er prix Pétrarque de l'essai France Culture/Le Monde* (2012) for his study *Énigm es et complots. Une enquête à propos d'enquêtes* (Paris: Gallimard, 2012).

As reflected in the themes examined in *Énigmes et complots*, Boltanski has recently embarked upon a critical study of the construction of the modern European nation-state, notably in terms of its systemic capacity to reduce the multiple uncertainties permeating social life. One key issue with which he has been grappling in this context is the question of the extent to which the tension-laden project of the European nation-state has triggered the emergence of 'new forms of representation' in the humanities and social sciences.

Major Works and Contributions

Boltanski has produced a large number of single-authored and co-authored books, edited and co-edited volumes, book chapters, and journal articles. In addition, he has written and published poetry, and more recently, theater plays. For the sake of brevity, the summary provided in this section shall focus on his most influential sociological works.

I

Les cadres. La formation d'un groupe social (Paris: Minuit, 1982) [*The Making of a Class. Cadres in French Society* (Trans. Arthur Goldhammer, Cambridge: Cambridge University Press, 1987)] (Boltanski, 1982; see also Boltanski, 1987[1982]).

As mentioned above, this book is based on the thesis for which Boltanski – under the supervision of Pierre Ansart – was awarded a *Doctorat d'État* in 1981. It provides an in-depth study of *les cadres*, that is, of a powerful social group made up of business leaders, managers, directors, chiefs, supervisors, and executives. One of the defining features of this group is that it projects the image of *a new class*, which is neither bourgeois nor proletarian. Its members may be described as 'highly competent,' 'highly skilled,' 'highly motivated,' and both politically and economically 'highly influential.' Yet, far from portraying them as a homogenous cluster of social actors, Boltanski stresses their *internal diversity*. He does so by drawing upon the information provided in numerous interviews conducted with representatives of this group, enabling him to deconstruct the myth that the emergence of *les cadres* can be regarded as a quasi-natural outcome of social, economic, and technological progress.

One of Boltanski's most significant achievements in this study is to have demonstrated the immense internal heterogeneity, along with the profound structural fragility, characterizing *les cadres*. His fine-grained analysis illustrates that the portrayal of this social group as a uniform and homogenous collective force, as well as its triumphalist celebration as the protagonist of a new meritocratic era based on prosperity and progress, must be rejected as a reductive misrepresentation of what is – in reality – a highly complex, heterogeneous, and volatile assemblage of actors.

Critics may have plausible reservations about the Franco-centric – and, hence, geographically and sociopolitically limited – scope of this enquiry. Indeed, the English translation of the original French *La formation d'un groupe social* (*The Making of a Social Group*) into *The Making of a Class* may – contrary to Boltanski's intentions – convey the misleading impression that *les cadres* form a social class, rather than a social group. Such an assumption seems untenable, given the fragmented and unstable constitution of their material and symbolic resources for action, of their internal organizational structure, and of their members' trajectories. In the contemporary era, a significant sociological challenge consists in exploring the extent to which *les cadres* continue to play a pivotal role in shaping social, economic, political, and ideological developments both in and beyond France.

II

L'amour et la justice comme compètences. Trois essais de sociologie de l'action (Paris: Métailié, 1990) [*Love and Justice as Competences* (Trans. Catherine Porter, Cambridge: Polity, 2012)] (Boltanski, 1990; see also Boltanski, 2012[1990]).

This book is of crucial importance in that it is one of the first works marking Boltanski's unambiguous *rupture* with the sociological approach developed by his academic mentor, Pierre Bourdieu. To be precise, it is Boltanski's first major single-authored study that makes an explicit attempt to challenge the arguably scientistic, positivistic, and fatalistic presuppositions underpinning Bourdieu's 'critical sociology.' In essence, this treatise accomplishes this by arguing that people care a great deal about justice. To be exact, Boltanski starts from the assumption that ordinary actors engage – *enthusiastically and critically* – in everyday disputes over different – *and, in many respects, competing* – conceptions of justice. It is particularly in situations in which people's sense of justice is challenged, affronted, or disturbed that they are likely to engage in subtle or open confrontations with others. Unlike Bourdieu, however, Boltanski posits that – instead of acting mainly in strategic, instrumental, utility-driven, or calculating ways – subjects capable of reflection and justification are able to engage in intersubjectively constituted processes of discourse and argumentation, thereby raising claims to validity in relation to different sets of normativity.

People's practical construction of, intuitive immersion in, and critical engagement with '*regimes of justice*' can be considered central to the value-laden unfolding of social life. No less important, in this respect, is the socio-ontological role of what Boltanski refers to as the '*regime of peace*' and the '*regime of love*' (*agapè*), whose existence is due to the fact that some actions are selfless and gratuitous. What all of these grammatically structured regimes of action – between which people, in their everyday lives, move back and forth – have in common is that they require its protagonists to refuse to draw on their *capacity for violence*, which can manifest itself in various – notably, physical, symbolic, and structural – forms of power.

As members of a 'common humanity,' we are equipped with the normative capacity to establish 'orders of worth' in the pursuit of the 'common good,' which transcends the divisive logic of competitive position-taking and merely strategic performativity. One of the main contributions of Boltanski's *Love and Justice as Competences*, therefore, is to have shed light on the *moral foundations of society* by taking seriously people's ability to engage in the construction of *everyday forms of normativity*. In other words, this book is a powerful reminder that our capacity to mobilize the reflexive resources embedded in our critical capacity permits us to build meaningful social relations based on a genuine concern with justice, love, and reciprocity.

III

De la justification. Les économies de la grandeur (avec Laurent Thévenot, Paris: Gallimard, 1991) [*On Justification. Economies of Worth* (with Laurent Thévenot, trans. Catherine Porter, Princeton: Princeton University Press, 2006)] (Boltanski and Thévenot, 1991; see also Boltanski and Thévenot, 2006[1991]).

This study provides numerous useful insights into the pivotal role that processes of justification play in the construction of social life. These can be synthesized in terms of the following levels of analysis:

1. *Ordinary actors are equipped with critical, moral, and judgmental capacities.* Owing to their ability to participate – actively and reflexively – in the meaning- and value-laden construction of different forms of sociality, their claims to objective, normative, or subjective validity are irreducible to mere epiphenomena of an interest- and power-laden struggle for legitimacy in field-specific – and, hence, positionally determined and dispositionally reproduced – realities.

2. *Any attempt to construct a hierarchy between 'ordinary knowledge' and 'social-scientific knowledge'* is epistemologically erroneous, methodologically counterproductive, sociologically untenable, politically patronizing, and philosophically fatalistic. To be sure, the point is not to deny that there are substantial qualitative differences between 'scientific analysis' and 'common sense.' It is crucial, however, to concede that these two levels of epistemic engagement with specific aspects of reality are not as far apart as they may appear at first glance. Instead of undertaking a clear-cut 'epistemological break' with the doxic illusions of common sense, the challenge consists in exploring the extent to which ordinary people's critical capacity constitutes a precondition for, rather than an obstacle to, the possibility of reflection and justification in all normatively codified settings of social interaction.
3. *All activities of justification have both grammatical and processual dimensions*, which can be empirically studied and conceptually grasped. Given their *grammatical* constitution, activities of justification are structured by context-specific logics of rationalization, argumentation, and valorization. Given their *processual* constitution, the underlying objective, normative, or subjective parameters mobilized in order to justify a belief or an action are not only in a constant state of flux, but also contingent upon the changing sets of circumstances in which they are applied by those making claims to validity and aiming to obtain empowering degrees of legitimacy. Different *cités* (polities) may be regarded as idiosyncratic *mondes* (worlds) capable of establishing different *grandeurs* (orders of worth) with different conceptions of *bien comun* (common good), whose validity can be confirmed or undermined by means of different *épreuves* (tests). Irrespective of the spatiotemporal specificity of a social situation, there are no practices of meaning- and value-laden interaction without both grammars and processes of justification.
4. *There are multiple normative orders with corresponding regimes of justification and modes of evaluation*. Six 'worlds', with corresponding 'orders of worth,' are particularly important: 'the inspired world,' 'the domestic world,' 'the civic world,' 'the world of opinion and fame,' 'the world of the market,' and 'the industrial world.' These 'worlds' possess both a '*quotidian*' and a '*metaphysical*' dimension:
   a. Their '*quotidian*,' and thus '*ordinary*,' constitution is reflected in the fact that these 'worlds' permeate the normative structure of *people's everyday practices*, as they find themselves immersed in different *regimes of action and justification* when navigating their way through the social universe. The experiences of passion ('inspired'), trust ('domestic'), solidarity ('civic'), recognition ('fame'), exchange value ('market'), and productivity ('industry') are built into 'orders of worth' by means of which actors engage with, and attribute meaning to, reality on a day-to-day basis.
   b. Their '*metaphysical*' or simply '*philosophical*' constitution is expressed in the fact that the systematic concern with the ontological significance of these 'worlds' can be traced back to the writings of classical, social, and political thinkers: St. Augustine ('the inspired world'), Jacques-Bénigne Bossuet ('the domestic world'), Jean-Jacques Rousseau ('the civic world'), Thomas Hobbes ('the world of fame'), Adam Smith ('the world of the market'), and Henri de Saint Simon ('the industrial world').
5. *Social actors are obliged to possess a certain degree of realism when engaging in disputes*. Put differently, people's participation in the normative construction of social life is inconceivable without their competence to *assess* what is possible, and what is not possible, when faced with a given set of materially and symbolically organized circumstances. People's capacity to be *realistic* in terms of what they can, and cannot, achieve within particular situations is a praxeological precondition for their ability to make judgments about – and, if required, take decisions in relation to – specific issues at stake in changing settings of interaction. Just as they are obliged to make compromises, they are expected to be able to cope with the fact that overt or hidden conflicts form an ineluctable component of social existence. Since, in their everyday lives, they are constantly required to position themselves in relation to normatively codified forms of action, they cannot escape the need to engage in processes of justification.

IV

La souffrance à distance. Morale humanitaire, medias et politique (Paris: Métailié, 1993; Paris: Gallimard, 2007 (Extended version)) [*Distant Suffering: Morality, Media and Politics* (Trans. Graham D. Burchell, Cambridge: Cambridge University Press, 1999)] (Boltanski, 1993; see also Boltanski, 1999[1993]).

This book provides an interdisciplinary analysis of 'distant suffering,' that is, of the experience and effects of perceiving processes of human grief and misery 'from a distance.' Perhaps, the most fundamental sociological issue with which Boltanski grapples in this study is the question of how human actors react when exposed to spectacles of suffering, while being geographically remote from the locations in which tragic or catastrophic events occur. Seeking to respond to this question, Boltanski unearths various sociological, political, moral, psychological, and fictional accounts concerned with the impact of 'distant suffering' upon those who experience it.

The book comprises three main parts. In Part I, entitled 'The Question of the Spectator,' Boltanski explores the normative issues arising from a set of principles and practices to which he refers as 'the politics of pity.' In Part II, entitled 'The Topics of Suffering,' Boltanski draws on literacy sources to examine several intermediary elements that influence the spectator's rational and emotional reactions to gruesome media portrayals. In Part III, entitled 'The Crisis of Pity,' Boltanski reflects on the implications of the fact that spectators can be converted into moral and political actors, particularly when passing value judgments on the alleged facts and happenings to which they are exposed via the media.

In the digital age, those who have direct and regular access to the mass media are habitually exposed to horrific images – such as starving children, bombed villages, war, genocide, and mass graves. It is far from clear, however, what it means to respond accurately and responsibly to such scenarios. For Boltanski, there is no doubt that, in order to overcome

a paralyzing state of sensationalism and voyeurism, spectators must rise above mere feelings of empathy and compassion. The 'politics of pity' is unsatisfactory in the sense that it encourages consumers of mediated misery to focus on the spectacle of suffering, thereby requiring them to observe the unfortunate, rather than to scrutinize – let alone to act upon – the socio-historical roots behind their deprivation. Boltanski, therefore, urges his readers to imagine possibilities of action and thereby challenge the constraining limitations, and detrimental consequences, of the largely passive consumption of information. Granted, the shift from a potentially disempowering 'world of representation' to a genuinely empowering 'world of action' is complex. Yet, the Boltanskian idea of a political and moral sociology cannot be dissociated from the conviction that subjects capable of reflection and justification are able to mobilize their critical resources in order to engage in normatively defensible and performatively empowering forms of action.

V

Le nouvel esprit du capitalisme (avec Ève Chiapello, Paris: Gallimard, 1999) [*The New Spirit of Capitalism* (with Ève Chiapello, Trans. Gregory Elliott, London: Verso, 2005)] (Boltanski and Chiapello, 1999; see also Boltanski and Chiapello, 2005[1999]).

This book provides a cutting-edge analysis of the emergence of what Boltanski and Chiapello describe as the 'new spirit of capitalism' in the late twentieth century. Shortly after its original publication in 1999, this study became a bestseller in France. According to Boltanski and Chiapello's analysis, we can distinguish *three spirits of capitalism*:

- The *first spirit*, prevalent in early modern societies, can be characterized as *family capitalism*, in the sense that it prioritizes the individual figure of the bourgeois proprietor and finds its ideological justification, above all, in the 'domestic city.' It is intimately interrelated with the *productive ethos* of Weber's famous Protestant Ethic. Sweeping away the rigid social, political, and economic structures of feudal-absolutist formations, the constitutive component of the 'first spirit of capitalism' is *productivism*.
- The *second spirit* can be referred to as *industrial or organizational capitalism*, epitomized in the protagonist role of 'the manager,' whose societal function is associated with 'organization man.' Emerging in response to the crisis of 1929–30, it is composed of a combination of *Fordist industrialism* and *Keynesian interventionism*, which may be interpreted as a trade-off between Rousseau's 'civic city' and St. Simon's 'industrial city.' The societal constellation generated by this historic settlement had two major consequences: (a) it contributed to enhancing the acquisitive power of the working classes in particular and people's chances to benefit from upward social mobility in general; and (b) it contributed to the rise of a relatively autonomous salaried professional labor force, especially in the liberal professions, arts and sciences, and public sector.
- The *third spirit* manifests itself, most clearly, in the *city of projects*, in which market-driven principles – such as 'flexibility,' 'adaptability,' 'creativity,' and 'mobility' – play a pivotal role in developing an ever-more elastic, and seemingly forward-looking, capitalist system. Also described as the *new spirit of capitalism*, it is inextricably linked to the rise of neoliberalism and neomanagerialism, especially from the 1970s onward, indicating the restoration of large-scale *market discipline* along with a shift toward the increasing *financialization* of capital flows. One of the paradoxical achievements of this 'new spirit' is to have succeeded in appropriating the subversive forces that sought to undermine the legitimacy of capitalism for its own purposes. The elastic and flexible nature of this 'new spirit' emanates from capitalism's capacity to promote and integrate discursive processes of debate and critique, thereby ensuring that, as a politico-economic system, it is both structurally and ideologically highly adaptable. The idea of *dominating by change* is essential to contemporary forms of social domination.

The rise of the 'network man' illustrates not only the emergence of a new systemic and ideological *modus operandi* of capitalism, but also its new spirit's capacity to take seriously four sources of indignation: *inauthenticity*, *oppression*, *misery and inequality*, and *egoism*. The former two were central objects of different versions of *artistic critique* and the latter two were principal matters of concern under the umbrella of *social critique*. It is one of Boltanski and Chiapello's noteworthy achievements to have demonstrated, with considerable empirical evidence and conceptual precision, that most contemporary forms of capitalism possess the capacity to *incorporate* normative processes based on critical discourse into their mode of functioning. In this sense, categorical openness to debate, controversy, and constant re-assessment has been converted into one of the normative cornerstones underlying the 'new spirit of capitalism.'

VI

La condition fœtale. Une sociologie de l'engendrement et de l'avortement (Paris: Gallimard, 2004) [*The Foetal Condition* (Trans. Catherine Porter, Cambridge: Polity, 2013)] (Boltanski, 2004; see also Boltanski, 2013[2004]).

Undoubtedly, this is one of Boltanski's most controversial books – possibly, because it deals with one of the most contentious issues in contemporary society: *abortion*. In this study, Boltanski draws upon accounts and statements collected from hospital settings as well as upon in-depth interviews conducted with women who have undergone abortions. In his insightful socio-philosophical interpretation of the discursive data upon which this enquiry is based, he directs his readers' attention to the profound *ambivalence* that appears to be built into abortion as a social practice. To be precise, for Boltanski, abortion exposes a contradiction that is inherent in all human life forms: on the one hand, we assume that individual human beings are *unique* and *distinctive*; on the other hand, we are confronted with their *replaceable* and *disposable* nature, without which there would be no demographic renewal and no societal regeneration.

Boltanski, therefore, proposes to examine the ways in which human beings are engendered by dissecting the symbolically mediated controls and constraints that are imposed upon them by society, of which they can become fully-fledged members

only to the extent that they are both willing and able to share its – normatively charged – conception of species-constitutive existence. On this view, a fetus is not a human being 'in itself,' ensconced within the female body, but, rather, a human being 'for itself,' to the degree that it is *symbolically constructed* and *discursively considered* as such by the members of a given society. For Boltanski, one twofold categorization is particularly important in this regard: the *project fetus* and the *tumoral fetus*. The former is desired by its parents, who attribute positive characteristics – such as 'meaningfulness,' 'fulfilment,' 'love,' and 'life plans' – to its existence. The latter is deprived of the privilege of forming an integral element of a parental endeavor and, in extreme-case scenarios, may be reducible to a nameless, replaceable, and undesired form of being, whose non-existence is preferred to its existence by those who have the power to decide over its future.

In the human world, then, sexual reproduction is never simply a *biological* affair but always also a process of *social* construction, especially in terms of how it is both interpreted and regulated by members of particular cultural life forms. Boltanski demonstrates, in a neo Durkheimian fashion, that every *social order* constitutes a *moral order*: a set of interrelated practices performed by ethically responsible actors whose decisions – irrespective of whether these are made consciously and unconsciously – have normative implications both for those who undertake them and for those who are, directly or indirectly, affected by them. Whatever one makes of Boltanski's analysis, owing to the contentious nature of this subject, *The Foetal Condition* cannot fail to challenge – and, in some cases, irritate – those contributing to contemporary controversies concerning abortion.

VII

De la critique. Précis de sociologie de l'émancipation (Paris: Gallimard, 2009) [*On Critique: A Sociology of Emancipation* (Trans. Gregory Elliott, Cambridge: Polity, 2011)] (Boltanski, 2009; see also Boltanski, 2011[2009])

Arguably, *On Critique* is Boltanski's most philosophical book. It provides an in-depth analysis of the conceptual underpinnings of the 'pragmatic sociology of critique,' focusing on the following six key dimensions:

1. Boltanski reflects on the task of *critical theories*. One of their vital concerns is the sustained effort to scrutinize the causes, symptoms, and consequences of *power relations* within particular historical contexts, especially those that are entrenched in societal systems of domination. In this respect, a fundamental difference between Bourdieu and Boltanski becomes evident. According to the former, ordinary people are largely *unconscious* of the workings, and essentially *naive* about the implications, of power relations. According to the latter, ordinary people are not only *conscious* of, and *realistic* about, power relations but also able to problematize the tangible implications of their existence. For Bourdieu, it is the task of 'critical sociologists' to uncover the underlying mechanisms that determine the asymmetrical structures permeating the interest-laden practices of *strategic agents*, who compete for material and symbolic resources. For Boltanski, by contrast, it is the mission of 'sociologists of critique' to recognize that human beings are *moral and reflexive actors*, whose critical capacity permits them to assess – and, if necessary, justify – the normative validity of their performances.
2. Boltanski aims to *reconcile Bourdieu's critical sociology with his own pragmatic sociology of critique*. Thus, he seeks to combine and cross-fertilize two seemingly antagonistic approaches. The former appears to advocate *social determinism* and *positivist scientism*, favoring the epistemic capacities of scientists over those of everyday actors, who seem to be deluded by doxic preconceptions based on common sense. The latter appears to endorse *social pragmatism* and *interpretivist normativism*, proposing to take ordinary people seriously in terms of both their performative capacity to shape the world and their discursive capacity to provide reasonable justifications for their beliefs and actions. Rather than conceiving of these two sociological approaches as diametrically opposed and irreconcilable, Boltanski aims to demonstrate that useful insights can be gained not only from comparing and contrasting, but also from combining and integrating, these two paradigmatic frameworks.
3. Boltanski grapples with the principal functions of *social institutions*. Their most essential task, it seems, consists in producing solidified – or, at least, seemingly solidified – realms of social interaction, enabling humans to cope with the uncertainty inherent in all worldly life forms. Boltanski draws an important distinction between 'world' ('*monde*') and 'reality' ('*réalité*'). While the former encompasses 'everything that is the case,' the latter comprises 'everything that is constructed.' Put differently, the world is 'everything that happens *to* people,' while reality is 'everything that is constructed *by* people.' To the extent that institutions convert our encounter with the world into an experience founded on the illusion of relative certainty, they can be regarded as a *conditio sine qua non* of the material and symbolic construction of reality. Institutions, therefore, constitute 'bodiless beings' that fulfill the task of defining what Boltanski calls 'the whatness of what is' or, to be exact, 'the whatness of what appears to be.'
4. Boltanski examines the role of *critique* in the normative consolidation of social life. Critique constitutes a driving force of historical change: it permits both individual and collective actors to shape the development of society in accordance with their discursively articulated search for principles that are defensible in terms of their practical worth and normative validity. For Boltanski, two registers of action are crucial in this respect. On the one hand, the *practical register* is characterized by relatively *weak and rudimentary levels of reflexivity*, presupposing a considerable tolerance for differences and discrepancies, as well as sustaining a set of codified arrangements that guarantee the reproduction of society. On the other hand, the *metapragmatic register* is marked by rather *elevated and differentiated levels of reflexivity*, involving an implicit or explicit reference to the normative force of critique and, at the same time, allowing for the articulation of two metapragmatic forces: *confirmation* and *justification*. People's ability to confirm and justify the legitimacy of their actions is central to their capacity to participate in the construction of normatively regulated constellations.

Confronted with *hermeneutic contradictions* emanating from the potential discrepancies between 'world' and 'reality,' human actors are in a position to question the apparent givenness of objectivity by facing up to the genuine arbitrariness of all forms of normativity. Illustrating the 'pragmatic' dimension of Boltanski's framework, it is crucial to recognize that processes of critique cannot be dissociated from three types of 'test' (*épreuve)* undertaken either to *reinforce* or to *undermine* the legitimacy of a specific ensemble of social constellations: (a) 'truth tests' (*épreuves de vérité*), (b) 'reality tests' (*épreuves de réalité*), and (c) 'existential tests' (*épreuves existentielles*). From a Boltanskian perspective, the emancipatory transformation of society is inconceivable without a critical engagement with the normative constitution of reality.

5. Boltanski discusses the concept of *domination*. More specifically, he draws a distinction between two fundamental types of domination: *simple domination* or *primitive domination*, on the one hand, and *complex domination* or *managerial domination*, on the other.

   '*Simple forms of domination are monolithic* in the sense that, under their authority, control over a particular population is monopolized by a state or overarching institution. Here, people are deprived of fundamental liberties (such as freedom of speech, expression, and communication) as well as of basic rights (such as civil, political, social, economic, and human rights). Under regimes of 'simple domination,' the exercise of power is relatively *arbitrary* and unambiguously *asymmetrical*. Obvious historical examples of this type of domination include absolutism, fascism, and any kind of dictatorial government whose exercise of power is motivated by normative principles based on political authoritarianism.
   '*Complex forms of domination are polycentric* – or, in a more radical sense, even *centreless* – in the sense that, under their influence, power structures are circular, amorphous, volatile, and in a constant state of flux, lacking an institutional or ideological epicenter. Here, people's essential liberties and rights are not only largely respected, or even defended, but also instrumentalized in order to foster the legitimacy of the hegemonic political and economic system in place. Under regimes of 'complex domination,' the exercise of power is – at least in principle – *democratic* and – albeit, admittedly, to varying degrees – *criticizable*. Contemporary scenarios that can be described in these terms are *democratic–capitalist societies*, shaped by cultures and institutions based on political pluralism and, hence, by the fact that critique is incorporated into the routines of everyday life. For Boltanski, then, the emergence of the 'new spirit of capitalism' is inextricably linked to the possibility of *dominating by change*, which is based on categorical openness to criticism and, thus, on the capacity to obtain legitimacy by advocating the aforementioned neomanagerial ideals, such as 'flexibility,' 'adaptability,' 'creativity,' and 'mobility.'

6. Boltanski expresses his own view of the conditions underlying processes of human *emancipation*. In his eyes, these processes are based on individual or collective practices that *promote the critical project of a reduction in the material and symbolic privileges of dominant social groups* and thereby *contribute to a more balanced distribution of capacities for action*. To be sure, Boltanski does not propose a utopian blueprint envisaging the construction of a perfect society. Owing to the anthropological optimism that undergirds his writings, however, he dares to believe that the construction of a world based on emancipatory life forms is both desirable and possible. Such a world would not be determined by constraining sources of social domination, such as privilege, status, and authority. Rather, it would be shaped, above all, by people's purposive, cooperative, and creative capacities allowing for individual and collective experiences of self-realization.

VIII

Enigmes et complots. Une enquête à propos d'enquêtes (Paris: Gallimard, 2012) [*Mysteries and Conspiracies: Detective Stories, Spy Novels and the Making of Modern Societies*, trans. Catherine Porter (Cambridge: Polity, 2014)] (Boltanski, 2012; see also Boltanski, 2014[2012]).

In this book, Boltanski draws an analogy between two domains of modern writing, which, at first glance, do not appear to have anything significant in common: on the one hand, the development of two *literary genres*, namely *detective stories*, which are based on methodical enquiries, as well as *spy novels*, which are built around plots and conspiracies; on the other hand, the development of the *human and social sciences*, which are founded not only on systematic investigations but also on what may be described as the 'hermeneutics of suspicion.' Particularly important, in this regard, are the following three scientific disciplines: *psychiatry*, known for fabricating seemingly evidence-based conceptions of paranoia; *sociology*, inspired by the enlightening mission to uncover the underlying causal forces that determine both the constitution and the evolution of the social world; and *political science*, seeking to explain the origins of major historical events by reference to conspiracy theories.

Thus, what *detective stories* and *spy novels* have in common with the *human and social sciences* is not only the fact that they emerged – and underwent profound paradigmatic transitions – in the same *historical context*, that is, in the late nineteenth and the early twentieth centuries, but also the fact that they are driven by the ambition to shed light on the *mysteries and conspiracies* whose existence escapes people's ordinary perception of reality. Hence, they seek to call taken-for-granted assumptions about the world into question, by providing logically coherent accounts, and evidence-based explanations, of the multiple factors influencing different patterns of human action.

According to Boltanski, the most powerful institutional expression of the attempt to organize and unify reality by regulating and controlling the behavior of a population living within a given territory is the modern nation-state. Central to his socio-historical analysis in this book is the assumption that, in the modern age, speculations and suspicions about *conspiracies* became a motivational driving force behind both popular and academic conceptions of the exercise of power. Inevitably, the search for hidden sources of influence involved the ideological construction of a dichotomously constituted reality: on the one hand, an *official reality*, based on appearances, public performances, and superficial impressions; on the other hand, an *unofficial reality*, founded on underlying structures, hidden

causal mechanisms, and concealed social forces. What crime and spy fiction have in common with positivist conceptions of science, then, is that they presuppose a *discrepancy* between these two levels of reality: 'appearance' *versus* 'substance,' 'interpretation' *versus* 'explanation,' 'imagination' *versus* 'observation,' 'fiction' *versus* 'authenticity.'

By putting the works of major detective and spy novelists – such as G.K. Chesterton, Arthur Conan Doyle, John Le Carré, and Graham Greene – under sociological scrutiny, Boltanski demonstrates that their writings reveal fundamental features not only of fiction-based genre, but also of modern society, especially with respect to the reciprocal relationship between modern institutions and modern science. According to Boltanski, the nation-state's ambition to exercise unlimited control over the reality constructed within the boundaries of its territory is aimed at the *stabilization* of volatile sets of social relations. The binary distinction between 'normal' and 'deviant,' which undergirds this socio-political project of the state, is as central to detective and spy novels as it is to the functionalist spirit permeating the works of the founding figures of sociology – that is, the writings of Karl Marx, Émile Durkheim, and Max Weber.

Boltanski emphasizes that *detective stories* and *spy novels* are fundamentally different in the following sense: within the former, the state tends to be portrayed as essentially 'apolitical'; within the latter, the state tends to be conceived of as deeply 'political' or even as a 'war state.' Given the profound uncertainty permeating capitalist societies, which are characterized by processes of constant and rapid technological and demographic transformation, spy novels and the social sciences serve a complementary function: in the early modern era, the widespread diffusion of the term 'paranoia' is inextricably linked to the paradigms of 'conspiracy' and 'suspicion,' which inform the exploratory spirit pervading both spy novels and positivistically inspired social science – especially psychiatry, sociology, and political science. Boltanski has illustrated – with great skill and considerable eloquence – that the *hermeneutics of investigation*, which one encounters in detective stories, and the *hermeneutics of conspiracy*, which is central to most spy novels, contain significant historical and presuppositional similarities with the *hermeneutics of suspicion*, which lies at the heart of the founding disciplines of the human and social sciences.

Conclusion

Given the wide-ranging scope and scholarly originality of Boltanski's writings, it may hardly be surprising that he is generally regarded as one of the most prominent contemporary French sociologists. In fact, his considerable influence manifests itself in the emergence of an extensive secondary literature concerned with the multifaceted aspects of his oeuvre. His influence spans far beyond Francophone (see, e.g.: Bénatouïl, 1999a; Gadrey et al., 2001; Nachi, 2006; Negri, 1994; Susen, 2012; Thévenot, 2006) spheres of social and political thought. Indeed, his international impact on current academic debates is reflected, particularly, in recent and ongoing Germanophone (see, e.g.: Bogusz, 2010; Boltanski and Honneth, 2009; Celikates, 2009: esp. 136–157) and Anglophone (see, e.g.: Bénatouïl, 1999b; Blokker, 2011; Honneth, 2010; Susen, 2007: 7, 146n.8, 147n.31, 167n.5, 202n.89, 202n.93, 223–224, 227n.25, 228n.50, 229n.51, 229n.52, 271n.24, 319, 322, and 325; Susen, 2011b: 370; Susen, 2011a: esp. 447–450, 453–456, and 459–461; Susen and Turner, 2014; Wagner, 1999) controversies concerned with both the empirical and the conceptual significance of his various contributions to the humanities and social sciences. While it would be erroneous to reduce Boltanski's project to a mere – albeit sophisticated – response to the work of his academic 'patron,' Bourdieu, there is no doubt that his proposed paradigm shift from 'critical sociology' to a 'pragmatic sociology of critique' has opened hitherto unexplored intellectual avenues in the attempt to do justice to the pivotal role that critical capacity plays not only in the pursuit of sociology, but also, more fundamentally, in the daily construction of society.

Abstract

This article describes the borderline personality disorder (BPD) as defined in the DSM-IV and DSM-V classification system and points to the present major shift in the conceptualization of personality disorders. The present, dimensionally oriented classification of personality disorders stresses the pathology of the self and of the relationship with others as central organizing concepts regarding the severity of these disorders. Borderline personality organization is described as the structural intrapsychic organization of experience that explains the pathology of self and object relations characteristic of the BPD. The clinical differential diagnosis of this disorder, its etiological features, and treatment approaches with psychotherapeutic methods and psychopharmacological intervention completes this overview.

The borderline personality disorder (BPD) is a prevalent personality disorder in clinical psychiatric practice; its prevalence is approximately 1–2% of the general population, at least in the advanced English-speaking democracies. It shares with all personality disorders an enduring pattern of rigid and maladaptive behaviors and inner experiences that deviate significantly from cultural norms and lead to significant distress and/or impairment in patients' social life, work or profession, and intimate relations. The Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR) and DSM-5 (to be introduced in 2014) describe the following criteria for the specific features of the BPD (Table 1).

A Major Conceptual Shift

The committee developing the new classification of personality disorders for the forthcoming DSM-V started from several assumptions: first, that the DSM-IV classification had proved unsatisfactory because of the high comorbidity found regarding the various personality disorders, and the fact that the most frequent diagnostic conclusion, in clinical practice, was personality disorder NOS, that is, 'not otherwise specified.' Second, within the committee there continued an old dynamic tension between empirical researchers interested in developing classification systems for the personality characteristics of normal populations, on the one hand, and clinicians who were concerned about developing a classification system that would do justice to the personality disorder constellations found in clinical settings.

The dynamic tension between the researchers interested in the empirical studies of normal populations, relating them to the predominant prototypes of personality disorders, and clinical psychiatry trying to preserve what they saw as their confirmed experience of the validity of major categories described in DSM-IV, evolved in the direction of a compromise, that included an important, major new development, namely, the agreement on a common basic factor of all personality disorders, a factor that represented a major criterion for the assessment of the severity of any personality disorder: the integration or lack of integration of the *self*, that is, of normal identity, and the degree of normality or pathology in the relations of the individual with others (Bender et al., 2011). Here, what might be called the common sense observation that patients with personality disorders have difficulty in their comprehension and management of themselves and with their comprehension and management of the relationship with

Table 1 DSM-IV and DSM-5 diagnostic criteria for borderline personality disorder

A pervasive pattern of instability of interpersonal relationships, self-image, and affects marked by impulsivity beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following criteria:

1. Frantic efforts to avoid real or imagined abandonment. Note: Do not include suicidal or self-mutilating behavior covered in criterion 5.
2. A pattern of unstable and intense interpersonal relationships characterized by alternating between extremes of idealization and devaluation.
3. Identity disturbance: markedly and persistently unstable self-image or sense of self.
4. Impulsivity in at least two areas that are potentially self-damaging, such as spending, sex, substance abuse, reckless driving, binge eating. Note: Do not include suicidal or self-mutilating covered in criterion 5.
5. Recurrent suicidal behavior, gestures, or threats, or self-mutilating behavior.
6. Affective instability due to a marked reactivity of mood (for example, intense episodic dysphoria, irritability, or anxiety usually lasting a few hours and only rarely more than a few days).
7. Chronic feelings of emptiness.
8. Inappropriate intense anger or difficulty controlling anger (for example, frequent displays of temper, constant anger, recurrent physical fights).
9. Transient, stress-related, paranoid ideation, or severe dissociative symptoms.

significant others was recognized, for the first time, as a basic characteristic of personality disorders. The fact that this dimension could be explicated, operationalized, and clinically evaluated in terms of the degree of its disturbance satisfied both empirical dimensionalists, and, particularly, psychodynamic psychotherapists, who, for over 30 years, have observed, described, and utilized this dimension in their assessment and therapeutic approaches to personality-disordered patients (Kernberg, 1975, 1980).

In summary, the proposed DSM-V personality disorder model includes two fundamental assessments: criteria A the general level of personality functioning scale, including the assessment of self and of interpersonal functioning; and criteria B the diagnostic criteria for six selected specific categories of personality disorders.

The assessment of degrees of pathology of the experience of self includes the following components: (1) Identity: the experience of oneself as unique, with clear boundaries between self and others; self-esteem and accuracy of self-appraisal; capacity for, and ability to regulate the range of emotional experience. (2) Self-direction: the pursuit of coherent and meaningful short term and life goals; utilization of constructive and prosocial internal standards of behavior; ability to self-reflect productively. The assessment of interpersonal functioning includes: (1) Empathy: comprehension and application of others' experiences and motivations; tolerance of different perspectives; understanding of the effects of own behavior on others. (2) Intimacy: depth and duration of positive connection with others; desire and capacity for closeness; mutuality of regard reflected in interpersonal behavior. In short, the components proposed to be central to a personality functioning continuum are identity, self-direction, empathy, and intimacy and the corresponding scale differentiates five levels of impairment, going from nonimpairment (healthy functioning), to extreme impairment.

The diagnostic criteria for six specific personality disorders types: antisocial, avoidant, borderline, narcissistic, obsessive compulsive, and schizotypal, are defined by the level of personality functioning reflected by the self (the A criteria) and by the corresponding specific pathological personality traits (the B criteria).

Basic Underlying Structure of the BPD: Borderline Personality Organization

The term borderline personality organization corresponds to the common features of lack of integration of the self-concept and lack of integration of the concepts of significant others that characterize all severe personality disorders, including the BPD as a typical expression of this pathology.

'Borderline personality organization' is characterized by pathological identity formation (identity diffusion), primitive defensive operations, and varying degrees of pathology of internalized value systems in the setting of maintained but somewhat reduced reality testing marked by a decreased capacity for subtle and tactful evaluation of interpersonal processes, particularly in the setting of more intimate relations. This level of personality organization includes all the severe personality disorders seen in clinical practice. Typical personality disorders included here are the BPD, the schizoid, and schizotypal personality disorders, the paranoid personality disorder, the hypomanic personality disorder, hypochondriasis (a syndrome which has many characteristics of a personality disorder proper), the narcissistic personality disorder (including the malignant narcissism syndrome (Kernberg, 1992)), and the antisocial personality disorder. The antisocial personality, the syndrome of malignant narcissism, and many of the narcissistic personalities are characterized in addition by significant pathology of internalized value systems (Kernberg, 1989, 1992).

From a clinical standpoint, the syndrome of identity diffusion represents the dominant characteristics of borderline personality organization and, thus, of the severe personality disorders as a group, including the BPD. In particular, in the context of pathological aggression, we see a poorly integrated, superficial, and unstable sense of self and others, and limited affect dispositions marked by a combination of intensity and superficiality in the setting of the predominance of negative affects. These core features of the severe personality disorders reflect the splitting or primitive dissociation of an idealized 'good,' segment of experience from a 'bad,' paranoid one. Splitting mechanisms are naturally reinforced by other primitive defensive operations intimately connected with splitting (projective identification, denial, primitive idealization, devaluation, omnipotence, and omnipotent control). This entire constellation of defensive operations serves to distort interpersonal interactions, to create chronic disturbances in interpersonal relations, and to interfere with the capacity to assess other people's behavior and motivations in depth, particularly under the impact of intense affect activation. The lack of integration of the concept of the self interferes with a comprehensive integration of one's past and present into a capacity to predict one's future behavior and decreases the capacity for commitment to professional goals, personal interests, work and social functions, and intimate relationships.

The lack of integration of the concept of significant others interferes with the capacity for realistic assessment of others, for selecting partners harmonious with the individual's actual expectations, and for investment in others. The predominance of negative affect dispositions leads to an infiltration of sexual intimacy by excessive aggressive components. The outcome is, frequently, an exaggerated and chaotic interest in polymorphous perverse sexual practices as part of the individual's sexual repertoire. In more severe cases, we see a primary inhibition of the capacity for sensual responsiveness and erotic enjoyment. Under these latter circumstances, overwhelming negative affect states eliminate the very capacity for erotic response, leading to the severe types of sexual inhibition that are to be found in the most severe personality disorders.

The lack of integration of the concept of self and of significant others also interferes with the internalization of the early layers of the system of internalized values. This leads to a particularly exaggerated quality of the idealization of positive values and ideals and to an extremely persecutory quality of prohibitions. These developments lead, in turn, to a predominance of splitting mechanisms at the level of internalized value systems, with excessive projection of internalized prohibitions. At the same time, excessive, idealized demands for perfection further interfere with the integration of a normal superego.

The BPD and the schizoid personality disorder may be described as the simplest forms of severe personality disorders. These disorders reflect identity diffusion in the setting of the predominance of splitting mechanisms and can be seen as the 'purest' expression of the general characteristics of borderline personality organization.

Fairbairn (1954) described the schizoid personality as the prototype of all personality disorders and provided an understanding of the psychodynamics of these patients unsurpassed to this day. He described the splitting operations separating 'good' and 'bad' internalized object relations, the motivated self and object representations that comprise the split-off object relations, the consequent impoverishment of interpersonal relations, and their replacement by a defensive hypertrophy of fantasy life. In fact, in the course of psychoanalytic exploration, the apparent lack of affect display seen in the schizoid personality turns out to reflect severe splitting operations; extreme splitting leads to a fragmentation of affective experience, which 'empties out' interpersonal experience. At the same time, the internalized object relations of the schizoid personality have the split, persecutory, and idealized characteristics typical of the BPD (Kernberg, 1975).

The BPD presents structural and dynamic features similar to those seen in the schizoid personality, but in the borderline personality we see expression of this pathology predominantly in impulsive interactions in the interpersonal field (Akhtar, 1992; Stone, 1994). In contrast to the schizoid personality, where internal object relations are expressed in conscious fantasy life in the setting of social withdrawal, in the BPD the same widely split, internalized object relations are enacted in the interpersonal field. In fact, in the BPD, repetitive, powerfully motivated interpersonal behaviors often replace self-awareness. Episodic, intense, overwhelming affect states ('affect storms') and poor impulse control in the setting of identity diffusion are typical of the BPD, in marked contrast with the schizoid personality where we see apparent lack of affect and good impulse control.

It may well be that the descriptive differences between the schizoid and borderline disorders reflect temperamental differences. In particular, the borderline and schizoid personalities appear to differ across the dimension of extroversion and introversion, one of the important temperamental factors that emerges under different names in various models of classification.

The intensity of affect activation and the lack of affect control seen in the borderline personality, along with the high incidence of affective illness that characterizes this group, suggest the presence of a temperamental factor relating to affect regulation as a predisposing factor for development of BPD. At the same time, it is impressive how the degree to which the integration of negative and positive affect states obtained in the course of psychodynamic treatments brings about a marked toning down and modulation of affect response. The increase of impulse control and affect tolerance in the borderline personality seen as a result of successful treatment illustrates that splitting mechanisms play a central role in the pathology of affects seen in borderline personality (**Figure 1**).

Differential Diagnosis

The most frequent mistake, in our experience, consists in confusing the chronic emotional instability and affect storms of personality-disordered patients with a truly hypomanic or manic behavior. In the case of manic behavior, the differentiation is easier; here the clear loss of reality testing, the presence of hallucinations and/or delusions, or inappropriate social behavior usually leads to intervention by others to control the patient, interventions that are typical enough to confirm loss of reality testing and to warrant the diagnosis

Figure 1 Summarizes the relationships we have outlined that can be seen among the various personality disorders.

of a bipolar disorder. Therefore, the confusion between bipolar illness and BPD is usually reduced to cases of assumed hypomanic behavior used as the basis to diagnose bipolar II in patients.

In about 19% of patients with BPD, however, a comorbidity with bipolar disorder may be present, and the patient shows both severe, chronic affective instability and clear hypomanic episodes (Gunderson et al., 2006). To ascertain the presence or absence of BPD in these cases, it is helpful to evaluate the general nature of the patient's relationships with significant others. Cases of pure bipolar symptomatology do not show severe pathology of object relations during periods of normal functioning, and even chronic bipolar patients, who suffer from both manic episodes and major depressive episodes, maintain the capacity for relationships in depth, stability in their relations with others, and the capacity for assessing themselves and most significant persons in their life appropriately (Stone, 2006).

In contrast, in severe personality disorders with the syndrome of identity diffusion, there is a marked incapacity to assess others in depth, a lack of integration of the concept of self, with severe, chronic discrepancies in the assessment of self and others, and chronic interpersonal conflicts, together with the difficulty of maintaining stable commitments to work and profession, as well as to intimate relationships.

The differential diagnosis between an episode of major depression and a chronic dysthymic reaction in BPD is more difficult, but eminently feasible if enough time is available to clarify the four major areas of symptoms.

First are the psychic symptoms of a depressive spectrum of illness. In major depressions, there is a significant slowdown of the patient's thought processes and the patient's psychomotor behavior, severe depression of mood that varies between profound sadness to the total unavailability of any subjective sense of feeling – a sense of total freezing of all emotional experience in the most severe cases. Typically, thought processes are severely self-demeaning and self-accusatory – rather than focused on accusing and blaming others.

A second area of exploration of the differential diagnosis is the evaluation of the personality structure that predated the beginning of the depressed episode. Patients with severe narcissistic personality disorder, BPD, histrionic personality disorder, and masochistic/depressive personality disorder are prone to severe dysthymic reactions characterized by frequent days with symptoms of depression without reaching the intensity, consistency, and duration of major depressive episodes.

A third area of inquiry facilitating the differential diagnosis between major depression and characterologically based dysthymic reactions involves the following neurovegetative symptoms that point to major depressions: severe insomnia, particularly consistent early awakening hours before the usual waking time; loss of appetite with severe weight loss; consistent loss of sexual desire; possibly impotence in men and suspension of menstrual periods in women; chronic, severe constipation (considering, naturally, that this may be secondary to the use of antidepressive medication); a heightened sensitivity to cold temperature; and, in severe cases, a typical 'masklike' facial expression of severe depression.

A fourth area of diagnostic relevance for the evaluation of depression is the analysis of environmental triggers that may have preceded a depressive episode. Typically, in chronic dysthymic, characterological reactions, environmental conditions may trigger depressive reactions, and these environmental conditions are often remarkably minor, while the patient pays a disproportionate attention to their symbolic value. Major depressions usually do not show such a direct relationship between environmental triggers and depression, although the combination of strong genetic disposition and environmental triggers can occur.

In contrast to this picture in personality disorders, suicide attempts in the context of symptoms of severe depression are typical of major depressive disorders and require a careful diagnostic assessment of the conditions under which suicidal behavior occurred. The types of suicidality generally found in patients with personality disorders that we have just discussed can most often be treated with outpatient psychotherapy.

One other relatively frequent and often difficult differential diagnosis is that between a severe personality disorder, particularly a BPD or a narcissistic personality disorder functioning on an overt borderline level with antisocial features, and an attention deficit/hyperactivity disorder in adolescent or adult patients.

Etiology

BPD, in common with all personality disorders, is the outcome of a complementary series of neurobiological, psychodynamic, and psychosocial etiological features. While, at this time, competing theories of personality development and psychopathology would accentuate different features of this series, there probably is general agreement on the participation of all of them in determining the final outcome of the crystallization of a BPD. These features include

- Genetic disposition to abnormal activation of one or several affect determining neurotransmitter systems, particularly the dopaminergic, serotonergic, and/or noradrenergic systems.
- Genetic disposition (related or not to the alternation of affective neurotransmitter systems), of the structural aspects and/or functions of the prefrontal cortical control system, and reactive hyperactivity of the amygdala to negative stimuli.
- Temperamental hyperreactivity to negative affective stimuli, related to the genetic dispositions referred to.
- Insecure attachment, related to abnormal caregiver–infant interaction in the first few months and years of life.
- Exposure to and/or victimization by physical and/or sexual abuse.
- Severe familial disorganization and unpredictability, blurring of generational boundaries, and early chaotic interactions with close family members.
- Strong predominance of the negative segment of intrapsychic experience, in contrast to a weak segment of internalized satisfactory emotional experiences, leading to persistence and dominance of primitive splitting, and related defensive mechanisms.
- Fixation, as consequence of all above features, of the internalized world of object relations and the self at the pathological organization of identity diffusion, the basic characteristic of severe personality disorders.

Present day research on the pathology of the neurobiological features and the psychopathological constellations of BPD is attempting to assess their relative importance and interrelatedness, their modifications in the course of treatment, and their implication for the strategies of treatment indications and techniques.

Treatment

The treatment of the BPD is essentially psychotherapeutic. There are several specialized psychotherapies available with evidence-based efficacy, outlined below. Psychopharmacological treatment has an auxiliary function and is only indicated in combination with one of these psychotherapeutic approaches.

Psychotherapies for this condition may be classified into psychodynamic and cognitive behavioral treatments.

Psychodynamic psychotherapies	*Cognitive behavioral psychotherapies*
● Supportive psychotherapy (SP) ● Mentalization-based psychotherapy (MBT) ● Transference-focused psychotherapy (TFP)	● Dialectic behavior therapy (DBT) ● Schema-focused psychotherapy (SFT) ● systems training for emotional predictability and problem solving (STEPPS)

Additional treatments include the integrative general psychiatric management, and several other approaches with less empirical research support. Recent comparative meta-analyses of these treatments – the Cochrane collaboration – conclude: "There are indications of beneficial effects for both comprehensive psychotherapies as well as non-comprehensive psychotherapeutic interventions for BPD core pathology and associated general psychopathology. DBT has been studied most intensely, followed by MBT, TFP, SFT, and STEPPS. However, none of the treatments has a very robust evidence base, and there are some concerns regarding the quality of individual studies. Overall, the findings support a substantial role for psychotherapy in the treatment of people with BPD but clearly indicate a need for replicatory studies."

From a practical viewpoint, clinical experience indicates that not all patients respond to all treatments, and selected patient subgroups may respond to some treatments but not to others. In general, when the predominant symptoms are circumscribed to one or several specific problems, such as, suicidal or para-suicidal attempts, specifically focused emotional crises, impulsivity or dissociative reactions, cognitive behavioral approaches, particularly dialectic behavior therapy, would seem the first treatment of choice. When general life problems dominate the clinical picture, such as, failure or breakdown in work or profession, in intimate love relations or a patient's social relationships, a psychodynamic approach may become the first priority. Mentalization-based psychotherapy focuses on patients' learning realistic ways to appreciate their own mental states and the mental states of significant others, and evinces a broad spectrum of patients able to benefit from it. Transference-focused psychotherapy is the only treatment geared to modify the basic pathological personality structure of BPD patients, and may present the optimal indication for patients with severe distortion of all their psychological functions in the areas of work, or profession, love and sex, and social relations. This approach is focused directly on the syndrome of identity diffusion, the basic pathology of the self system and internalized relations with significant others. At this time, research is proceeding regarding the process, mechanisms of change, indications and contraindications of BPD psychotherapies, as well as of the underlying psychological and neurobiological determinants of BPD pathology, and patients' response to treatment.

Regarding psychopharmacologies contributions to the treatment of BPD patients, no one specific medication represents a treatment of choice. Probably about one-third of patients respond to medications over a period of months or years. The main group of medications that have proven helpful to reduce BPD symptoms include antidepressive medications, particularly the Selective Serotonin Re-uptake Inhibitors SSRI group; low doses of atypical antipsychotic medication, particularly risperidone, olanzapine, and aripiprazole; and mood stabilizers, particularly lithium carbonate, valproate, and carbamazepine. SSRI medication has particular indications for affective dysregulation and impulsive behavioral symptoms. Low dose atypical antipsychotic medication also targets these same symptoms, and is particularly indicated for cognitive perceptual symptoms. Mood stabilizers have a relatively secondary indication for some patients with affective dysregulation and impulsivity.

Abstract

This article examines the frontiers and borders in which anthropologists have been interested, from cultural borders which separate and connect different worlds of meaning and identity to borders that mark out geopolitical space and borders that order social relations and define membership of 'community.' It shows how these cultural, territorial, and social dimensions often overlap and how all three have been integral to an anthropology of borders. The article suggests that the social sciences have increasingly converged in their emphasis on borders as relational and dynamic, no longer confined to political margins but embedded throughout everyday life, a perspective that anthropology has long been adept at exploring.

Introduction

The anthropology of borders has been characterized by three perspectives which, though they overlap, can be identified by their relative emphasis on the cultural, territorial, and social dimensions of borders. These three dimensions were sometimes seen as different types of border, and at other times as aspects of a single border. Indeed, anthropologists are rarely interested in only one type of border or the other, and in many cases the borders they analyze have all three dimensions. Much discussion has thus revolved around how these dimensions intersect, diverge, or coincide. Building on these three perspectives, borders have increasingly been interpreted as a dynamic process, shifting through time and space, and made and remade through everyday practice. Many contemporary border researchers thus no longer take borders for granted and then examine their effects, but instead ask how, why, and when borders are shaped, endure or recede through the agency of those who live and cross there. Answers to these questions not only contribute to wider social and cultural theory but also address current debates about global security and mass mobility.

Anthropologists have a long-standing interest in borders. In the past, this was reflected in a concern with bounding their field of study. Cultural variation was considered a function of geographic and social isolation and early ethnographers advocated analyzing this diversity by treating each social unit as a discrete organic whole. But as the mobility of people dramatically increased (with urbanization, industrialization, etc.), culture contact rather than cultural isolation became the focus of the day. Diffusionists and acculturationists had always been interested in culture contact, but their work was overshadowed and ultimately displaced by the rapid rise and supremacy of functionalism. The belated 'rediscovery' of the value of their insights for contemporary theoretical questions about global cultural interconnectedness indicates a major shift within the discipline: from a concern with what borders encompass to an interest in the borders themselves and the processes through which they emerge.

Frontiers

One way in which anthropologists originally approached the study of culture contact was through the concept of frontier. Etymologically, frontier means 'in front' and came to signify the process of expansion of a political entity (Febvre, 1973). Among its most influential proponents was Turner (1977: p. 3), whose 'frontier hypothesis' – first formulated in 1893 – claimed that "the existence of an area of free land, its continuous recession, and the advance of American settlement westward explain American development." Here, the frontier was the unequal meeting ground between 'civilization and savagery' whose domestication, Turner argued, fashioned the pioneering and independent spirit of the nation. Largely discredited now, Turner's frontier hypothesis was once among the most-debated problems in American historiography, not least because of its attempt to link space and time to the formation of national character. Other early approaches to frontier as a zone of cultural transition and overlap, or that examined the view from the frontier's 'other side' (which Turner had ignored), or that emphasized the magicoreligious aspect of frontier crossing (Van Gennep, 2010; chapter 2), have perhaps been more congenial to anthropology. For example, Bohannan (1967: p. xiii) saw frontier as a 'device' to view cultural and social changes, while Kopytoff (1987) used it to critique Eurocentric views of ethnogenesis in Africa by arguing that ethnic heterogeneity on the continent is better understood as a consequence of the cyclical proliferation of internal frontiers rather than as the result of colonial intrusion. More recently, Roitman's (2005) analysis of financial regulation in the Chad Basin sees this part of Central Africa, which is characterized by the multiple intersections of colonial, postcolonial, and other boundaries, as a discontinuous and shifting frontier zone of fiscal possibility and ambiguity predicated on the illegal border crossings of a 'population flottante.' According to Tsing (2005: pp. 27–29), such 'resource frontiers' are generated in the interstitial space between the legitimate and illegitimate where deregulation means that anything is possible, creating frontiers of 'unmapping' and 'wildness' that have become central to contemporary capitalism and a feature of neoliberal sovereignty (Chalfin, 2010).

Despite these differences and recent refinements, frontier often continues to be used as a synonym for borders, and 'borders, boundaries, and frontiers' are frequently listed together without obvious distinction unless the discussion is explicitly about definitions. Sometimes, it is also used to emphasize a zone of transition characterized by cultural

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12028-8

juxtaposition and intermingling, where differences meet, merge, blur, or coexist. It has been proved particularly effective as a trope in contexts of diaspora and transnational mobility, with their 'fuzzy frontiers' of identity and belonging, a usage anticipated in 1966 by Bohannan (1967: p. xviii) who noted how the frontier is no longer characterized solely by space but is 'all around us,' 'marked by the cultural selectivity of peoples and interest groups.' The frontier 'all around us' is the primary focus of many contemporary anthropologists as outlined below.

Some anthropologists have thus been principally interested in cultural borders (some would say cultural frontiers) in which different worlds of meaning and identity both collide and connect; while others have focused on territorial borders which mark out geopolitical space; and yet others on borders which order social relations and indicate membership of 'community.' All three have been integral elements in the emergence of an anthropology of borders and with the 'cultural turn' in the human sciences generally have been influential in the study of borders in other disciplines.

Cultural Borderlands

Borders have become a metaphor for the cultural flux and indeterminacy of much contemporary life. In anthropology, the border metaphor was introduced by critics of the classic anthropological view of culture as shared, consensual, and discrete. Often with personal experience of cultural contradictions – as members of sexual, ethnic, or other minorities – these critics sought ways to study the differences within and the spaces between cultures, ways that could incorporate the changes, inconsistencies, and incommensurabilities of everyday life. These intercultural spaces are often referred to as 'borderlands,' a usage that evokes the geopolitical and the metaphorical, the literal and the conceptual. In this view, borders and borderlands exist not just at the edges of the nation-state, but anywhere cultures meet (Rosaldo, 1989).

Borderlands are zones of cultural overlap characterized by a mixing of cultural styles. They are liminal spaces, simultaneously dangerous and sites of creative cultural production open to cultural play and experimentation as well as domination and control. The fusion of registers in borderlands may be ultimately empowering for those who inhabit these zones, but it need not always be so, as testified by the lives of many Mexican migrants in the American Southwest.

Not everyone agrees that it is helpful to extend the use of 'border' and 'borderland' in this way. When cultural encounters share some of the specific sociopolitical processes characteristic of borders between states, such as unequal access to official forms of power, the borderland metaphor may be appropriate. But where there is no strong analytical connection to state border processes, understanding of the border can become reductive and delocalized (Heyman, 1994).

Cultural differences and the juxtaposition of different worlds of meaning come to be emphasized at the expense of stressing inequalities of power. Heyman and others feel uneasy about this differential emphasis, reflecting wider tensions within the discipline over the relative prominence to be given to culture and power. The force of the image, they feel, takes over from the analysis.

In a sense, of course, borders are always metaphors, since they are arbitrary constructions based on cultural convention. Metaphors, moreover, are part of the 'discursive materiality of power relations' and in this respect no less concrete in their consequences than state borders (Brah, 1996: p. 198) as Vila (2000) has compellingly demonstrated in his narrative ethnographies of the Mexico–US border. Metaphorical and state borders are not, therefore, as far apart as some studies imply. In fact, the anthropology of borders has benefited from the productive interaction of approaches that emphasize one or the other. The following sections outline other anthropological analyses of borders from which the border-as-metaphor draws its force and resonance.

Territorial and Political Borders

State borders entail a mapping out in geographic space and recognition in international law. They mark the limits of sovereignty and of state control over citizens and subjects, limits that may be upheld by force or by the threat of force. They are often highly visible physically, which has led some scholars to refer them as 'real' borders in contrast to borders without territorial counterparts. This can be misleading, and the materiality of state borders should not blind us to their cultural and symbolic dimensions (just as we should not assume that cultural and symbolic borders automatically have no materiality).

Apart from the Mexico–US border, state borders have not until recently been subject to systematic comparative scrutiny by anthropologists. Where they did appear in ethnographic accounts, they often figured only as a backdrop to some other line of inquiry. Prior to the 1970s, even studies of the Mexico–US border rarely included the border as a variable in the analysis. As a result, the anthropology of state borders was slow to develop.

A fledgling 'school' of anthropological border studies briefly emerged at the University of Manchester, UK, in the 1960s, but subsequently fizzled out. During this period, several books appeared specifically with borders in their titles; each influenced by Max Gluckman who was Departmental Chair at that time (e.g., Cohen, 1965; Harris, 1972). Taken together, they began something that took another 20 years to bear fruit. But though these books did not problematize, the state borders near which their authors did research, and though they did not cross-refer to one another, they nevertheless identified some common themes in the political anthropology of borders which laid a solid foundation for contemporary anthropological analyses of nations and states. They pointed out, for instance, how proximity to a state border can intensify local conflicts, which can easily escalate into conflicts over nationality, a threat which only cross-cutting linkages (of kinship, common residence, and shared social and economic interests) help to keep in check. Understanding these borders thus requires local ethnographic knowledge, and not just the knowledge of state-level institutions and international relations, a fine-tuned sensitivity that is alert to cultural meanings and practice that remains central to the anthropology of borders today.

The value of localized studies for understanding how cultural landscapes are superimposed across social and political divides was first systematically developed by Cole and Wolf

(1974) whose field site in the Italian Tyrol was specifically chosen because its successive historical partitioning allowed them to explore the transformation of local political loyalties in relation to nation-building. What particularly interested Cole and Wolf about the South Tyrol was the durability of a cultural frontier long after the political borders of state and empire had shifted. National boundaries had clearly survived the demise of state borders, and remained important in everyday life. Despite their similarities, the two villages studied had followed a different political and cultural course since World War I. Villagers minimized these ideological and cultural differences in public encounters, but in private quickly resorted to ethnic stereotypes to explain the actions of the others. Cole and Wolf thus reiterate Barth's (1969) observation that ethnic boundaries may be maintained despite relations across them. Their major contribution, however, was in demonstrating the need to combine the study of local and extralocal influences to understand and explain this process.

Here, then, is an example of where ethnic boundaries result from, and evolve with, the rise and demise of state borders. Each can only be understood by reference to the other. In this respect, Cole and Wolf combined symbolic border studies (see Section Social and Symbolic Borders) with a political economy perspective that situates ethnographic knowledge of local boundaries within wider historical and political processes, a novel combination that marked an important transition in the anthropology of borders and heralded the beginning of a new form of inquiry. Subsequent anthropological research on national and international borders was to draw explicitly or implicitly upon this groundbreaking work (see Donnan and Wilson, 1999, for example). Anthropologists began to use their field research at state borders as a means of widening perspectives in political anthropology to encompass the formal and informal ties between local communities and the larger polities of which they are a part. Some studied border areas as a way of examining how proximity to an international border could influence local culture or could create the conditions that shape new rural and urban communities. Others focused on the voluntary and involuntary movement of people across borders as traders, migrants, and refugees. Yet others concentrated on the symbols and meanings which encode border life. The Mexico–US border, where the issues of underdevelopment, transnationalism, and the globalization of power and capital, among other aspects of culture, increasingly concern the growing number of historically informed and wide-ranging ethnographic accounts, offers excellent examples of all of these trends (see Alvarez, 1995, 2012).

Regardless of theoretical orientation or locale, however, most of these border studies have focused on how social relations, defined in part by the state, transcend the territorial limits of the state, and, in so doing, transform the structure of the state at home and in its relations with its neighbors.

Anthropological interest in how local border developments can have an impact on national centers of power and hegemony was partly stimulated by historical analyses of localities and the construction of national identities (e.g., Sahlins, 1989). Cole and Wolf's insistence on the need to view the anthropology of borders as historical anthropology is recalled. As the South Tyrol case so clearly shows, borders are spatial and temporal records of relationships between local communities and between states. Ethnographic explorations of the intersection of symbolic and state borders have salience beyond anthropology because of what they may reveal about the history of cultural practices and about the role of border cultures and communities in policy-making and diplomacy. This kind of research highlights the growing importance of a border perspective in political anthropology, a perspective in which the dialectical relations between border areas and their nations and states take precedence over local culture viewed with the state as a backdrop.

The next section outlines the work of some of the scholars whose innovative theorizing of the symbolic dimensions of social boundary making has provided a cornerstone to the anthropology of state borders worldwide.

Social and Symbolic Borders

One of the most influential theorists in the anthropology of borders has been Barth (1969), who argues that people may traverse group boundaries and maintain regular relations across them without affecting the durability and stability of the boundaries themselves. Barth's focus is on ethnic groups, which he argues are social constructions, the result of individuals strategically manipulating their cultural identity according to context, rather than the predetermined outcome of some objective list of culture traits. Membership of ethnic groups should thus be understood as based on self-ascription and ascription by others: individuals claim membership in a particular group and others confirm or question that claim. Attention is thereby drawn to the boundary between groups: to how and why people distinguish themselves from others, and to the rules of behavior that sustain such boundaries in the face of relations that transcend them. Barth's boundaries are above all 'social' boundaries: they may or may not have a territorial dimension, and cultural differences become significant only in so far as they are useful for organizing social relations.

Barth's work both revolutionized the study of ethnic groups and stimulated further research on borders. Some of this research demonstrates that borders mark affective and identificatory as well as structural and organizational disjunctures: those on the inside not only inhabit a separate social system from those on the outside but they identify themselves differently. Any social border is thus a consequence of the various possible relationships between these two dimensions on each side of the border as well as across it (Wallman, 1978). This highlights the relational nature of social boundaries, drawing attention to what they mean to people and to how they are marked. These are issues developed by Cohen (1985). Echoing Barth, Cohen suggests that borders are constructed by people in their interactions with others, from whom they wish symbolically to distinguish themselves. However, we cannot predict what the distinguishing features of these symbolic borders will be, or exactly where the lines will be drawn. Moreover, they may mean different things to different individuals, both to those within a border as well as those outside it. In fact, borders recognized by some may be invisible to others. The anthropologist's task is to uncover

these borders and their meanings in order to grasp what inclusion or exclusion entails.

Cohen has been criticized for devoting more attention to one side of the border than the other. For him, the significance of symbolic borders is that they allow people to retain a sense of distinctiveness in a world where the diversity of local communities is increasingly threatened by structural incorporation into wider political formations and global cultural styles. This inevitably leads him to emphasize what goes on within a border, since this is how he can identify the symbolic beliefs and practices that people deploy to mark and celebrate their sense of difference. When he does consider what lies beyond the border, it is often only to show how external events can be manipulated to symbolic advantage at the local level.

Similar criticisms have been leveled at Barth. As we have seen, Barth also emphasizes that boundary making involves both self-ascription and ascription by others. But he too tends to focus on only one side of the border, emphasizing internal identification rather than external categorization and the shaping influence of wider structures. This minimizes the relative power relations upon which the external ascriptive process depends, and underplays the fact that some people can impose their categorizations on other people. Relationships of domination and subordination can only be restored to theoretical centrality in border studies by recognizing those on one side of a border may be better able than those on the other side to determine where and how the line is drawn (cf. Jenkins, 1997). Indeed, we saw earlier that some anthropologists who focus on state borders have attempted to build this dimension into their analyses.

Conclusion and Convergence

Three reasonably distinct but mutually enriching streams in the anthropology of borders have been identified. All three show that anthropologists have brought to the study of borders an appreciation of what borders mean to those whose lives they frame. It is on this emphasis on how borders are constructed, negotiated, and viewed from 'below' that the three perspectives outlined here converge and on which the value and distinctiveness of an anthropology of borders largely depends. It is this that anthropology brings to the eclectic and interdisciplinary field that border studies have become, one increasingly characterized by a convergence of question, concept, and comparative approach. Anthropology's longstanding sensitivity to comparative worlds of identity and meaning, and to symbolic boundaries and cultural borderlands, arguably anticipated some of the questions, now engaging disciplines once principally preoccupied with 'realist' perspectives that emphasize borders of space, territory, and geopolitics. This has opened up these disciplines to new conceptual directions.

New perspectives have also opened up within the anthropology of borders, as well as new field sites in parts of the world previously underrepresented in borders research. Border ethnographies have proliferated, with case studies of colonial, precolonial, indigenous and pre- and postsocialist borders in eastern Europe, Africa, South and Southeast Asia, Central Asia, and North and South America bringing a welcome set of comparators to the borders of the European Union, Middle East, and Mexico–US that had long been paradigmatic in border studies. Thematic focus is now similarly diverse (for overview, see Wilson and Donnan, 2012) and while post-9/11 research is dominated by the relationship between borders, security, surveillance, and mobility (e.g., Chalfin, 2012; Cunningham, 2012; Cunningham and Heyman, 2004; Kalir and Sur, 2012; Smart and Smart, 2012), other novel ethnographic fields, such as health, bio- and eco-borders, maritime boundaries, and fiscal frontiers have also emerged.

But perhaps above all it has been the epistemological shifts, rather than the expansion of geographical and thematic focus, that characterize the last decade in the anthropology of borders. These have entailed an increasing emphasis on relationality as the critical feature of borders, echoing Wallman's (1978) approach and developing related strands within the other perspectives outlined above which emphasize the ubiquity and placelessness of borders rather than their locational fixity in space. The relative prominence attributed to territory, culture, and the social as elemental aspects of 'border' has altered, and the relationship between states and borders become loosened or detached altogether in some analyses even as the significance of the state for social boundaries is forcefully argued by others. Borders are now more likely to be seen as 'process' than as 'product,' the outcome of a fluctuating tension between dynamic relationships of inclusion and exclusion. This shift has been variously conceptualized within and beyond the anthropology of borders: as borderscape (Rajaram and Grundy-Warr, 2007), as bordering or b/ordering (Van Houtum et al., 2005) and as tidemark and borderness (Green, 2012). What these reconceptualizations of 'border' share in common is their insistence that 'the border' is not (or is not just) a particular physical space. Rather, the border is historically contingent, always in flux, and the momentary outcome of an "inherent contestability of the meaning of the border between belonging and non-belonging" (Rajaram and Grundy-Warr, 2007: p. xxviii). Border is thus better seen as 'bordering,' as verb rather than noun, whose traces should be understood as an ever-changing tidemark rather than as a fixed and predetermined line. Conceptualized in this way, 'border' is increasingly studied not as a once-and-for-all but as continuously emergent through the performative making and remaking of difference in everyday life through text, discourse, practice, and event. No longer just the limits of the political (Balibar, 2002: p. 92), borders are now 'all around us,' embedded in the practice of the ordinary life that anthropology has been so adept at exploring.

This current openness in border studies to transdisciplinary dialogue and convergence of perspective and approach suggests a new willingness to engage global comparison and the work of scholars in other fields, thereby rethinking disciplinary boundaries alongside our reconceptualizing of borders themselves.

Abstract

Ester Boserup (1910–99) was a strong proponent of an interdisciplinary approach to problems of international development. She made significant contributions through her studies of agriculture, population growth, informal work, rural–urban migration, polygamy, property rights, education, and urban employment. Boserup's book, *Woman's Role in Economic Development*, generally is acknowledged as initiating the formal field of study: Women in International Development. By demonstrating that women are often marginalized in the course of development rather than gaining from the process, her work helped shift the focus of development research from growth of income toward people's well-being and agency.

Ester Boserup (1910–99) summed up her research as focusing "… on the interplay of economic and noneconomic factors in the process of social change, both today and in the past, viewing human societies as dynamic relationships between natural, economic, cultural, and political structures, instead of trying to explain them within the framework of one or a few disciplines" (1999). Boserup's book, *Woman's Role in Economic Development* (1970), generally is acknowledged as initiating the formal field of study: Women in International Development (WID). While the WID field is interdisciplinary and built on the research and practice of numerous women and men, Boserup's contribution is substantial and helped shift research and policies to address women's work more thoroughly.

Boserup was born Ester Borgesen in Copenhagen, Denmark, 18 May 1910. She studied economics at the University of Copenhagen during the Great Depression (1929–35), which influenced her search for theoretical explanations of economic processes that went beyond the equilibrium approach. Her major field of study stressed theoretical economics but also allowed her to take courses in sociology and agricultural policy. While at the university, she married Mogens Boserup. After graduating, she worked for 12 years for the Danish government writing on regulations and agricultural policy in Europe. Her three children were born in this phase. From 1947 to 1957, Boserup worked in Geneva for the United Nations' Economic Commission for Europe and began collaborative work with the UN Food and Agriculture Organization (FAO). During this period, her research focus expanded to developing countries.

In 1957, Boserup and her husband left the UN and went to India for the *Asian Drama* research project with Gunnar Myrdal. Ester Boserup drafted chapters on agriculture, Gandhism, and development planning. Her travels in South and Southeast Asia exposed her to different types of farming and land tenure systems. She began to formulate her own concepts of the process of development that countered much of the received wisdom of the time; for example, she observed that labor was still a constraint in traditional agricultural systems so that the marginal product of labor could not be zero (or close to it) as commonly assumed and that rural–urban migration was often caused more by pull factors, such as attractive money incomes, than by push factors. In 1960, Boserup and her husband resigned from the *Asian Drama* project because their ideas about the development process had grown too far from Myrdal's.

For the rest of her life, Boserup worked as a consultant for organizations such as the FAO Trade Division in Rome and the Center for Industrial Development (later called UN Industrial Development Organization (UNIDO)). This was the period when she published her most influential works: *The Conditions of Agricultural Growth* (1965/1993) and *Woman's Role in Economic Development* (1970). She played a central role in the UN World Population Conference in Bucharest in 1974 and the first UN World Conference on Women in Mexico City in 1975. In the 1990s, she stopped participating in conferences because of her health, but she continued to be active in research and writing, stressing dynamic, interdisciplinary approaches to development issues, until her death on 24 September 1999 in Ascona, Switzerland.

Boserup's Theoretical Contributions

Boserup's works reflect her background in classical and neoclassical economics as well as interdisciplinary studies. In 1936, she began building her analysis with a comparison of Marx's theory of underconsumption and Keynes's theory of propensity to consume (1999). Boserup established her reputation as a researcher with *The Conditions of Agricultural Growth* in the mid-1960s. Her main thesis in this work is that technological change and property rights are endogenous. The book was published at a time when growth theory was dominated by neoclassical models that treated technology as exogenous. Boserup hypothesized that increasing population density led to transformation of the environment and introduction of new technology, in particular in a change of agricultural systems from shifting (slash and burn) techniques to use of the plow and irrigation. This view countered the Malthusian and neo-Malthusian positions on population growth that took the carrying capacity of the Earth and technology as given and predicted that continued population growth would lead to soaring prices for grain, wars, disease, and at best a return to subsistence survival for most people.

While Boserup's analysis was a bold break with much of the received wisdom of the time, it still contained elements of the linearity present in the works of writers like Marx and Rostow and implicitly posited a view of development as progress from family production to modernity characterized by labor specialization

and monetization of the economy. Statements that Boserup made at times in her writing, however, demonstrate that her views were actually more complex; she noted, for example, that reversals can occur such as the fall of the Roman Empire (1999). The complexity showed up more consistently in her interdisciplinary, dynamic approach rather than in addressing issues of nonlinearity and variety in development processes. Although there are differences in current views about what motivates technological change, the conceptualization of technology as endogenous has been a significant contribution to development theory. It is the basis of much of the new growth theory of the 1980s and 1990s, but new growth theorists are more likely to explain the technological adaptation in terms of human capital and positive externalities rather than population pressure.

Her book on agricultural growth gave Boserup the credentials in the academic community necessary to stir interest in her next major work, *Woman's Role in Economic Development* (1970). The timing was also good since activism among women was growing and interest in changing public policy was increasing among men and women. Boserup brought gender into development analysis as an integral factor that has remained central to much subsequent development work (Jaquette and Staudt, 2006; Tinker, 2001). She pointed out that both colonialism and modern development programs had frequently marginalized women from rights that they previously had.

She brought in her ideas from the agricultural growth book to identify shifting agriculture with low population density, tools such as the hoe, common property, and women taking an active role in subsistence farming. This system, common in Africa, she identified as a female farming system. She contrasted this with the system often found in more densely populated Asia of plowed fields, irrigated crops, and private property, which she termed a male farming system. She noted that the gender roles in economic activity were distinct in all the societies she studied and although considered 'natural' by members of each group, they varied across cultures – illustrating that the gender roles were constructed socially rather than being biological. Despite her awareness of these variations in occupation and time use by gender, Boserup focused on constructing a general view and downplayed the variation among agricultural systems. She stated that the agricultural system would tend to progress from the female farming, shifting system to the male farming, plowed system as population density increased. Continuing growth of population would then lead to more intensive farming of irrigated land by both women and men (a mixed system) (1970). Much of the research that had focused on women and gender at that time had been done by anthropologists who frequently used in-depth case studies as a methodological approach. As a trained economist, Boserup used the approach of collecting large amounts of data on the roles of women and men from many countries (mainly in sub-Saharan Africa and South/Southeast Asia) and making inferences – thus, the 12 figures and 64 tables in her book (1970, 1999).

Continuing Influence of Boserup's Pioneering Effort

Woman's Role in Economic Development has been cited often and has generated debate and controversy that has deepened our understanding of human development. The publication of the book in 1970 marks the beginning of the multidisciplinary WID field that brought together researchers, practitioners, and policy makers/advocates initially to work to integrate women into the development planning process (see Tinker, 1990). Boserup's work clearly demonstrated that she recognized that women had long been actively participating in the actual development process (Jaquette, 2001).

The WID field has evolved gradually. In the late 1980s, advocates concerned with global gender issues put forward a new gender and development (GAD) model to focus more on relative gender analysis of how women and men fare in the costs and opportunities associated with economic transformation policies and the process of globalization and how differences in age, class, religion, and location influence the results (Jaquette and Staudt, 2006). The distinction between WID and GAD has blurred in practice, and the field has centered more on issues of globalization and crisis as well as development policy. Significant critiques of *Woman's Role* were published by Huntington (1975) and Beneria and Sen (1981). Huntington challenged Boserup's classification of female and male farming systems and suggested that women in Africa had been in subordinate relations with men, more like peasants and aristocrats, long before the colonial period. Beneria and Sen acknowledged Boserup's contributions but critiqued the lack of clear theoretical framework, the dominance of the capitalist model of development in her work, and the lack of feminist analysis of women's subordination and their reproductive roles (1981). Boserup's publications also motivated the *Persistent Inequalities* volume (Tinker, 1990) that remains a leading contribution to the WID/GAD field. Debate continues both over the rhetoric of what to call this evolving field and appropriate theories and policies that recognize diversity and give voice to the people affected throughout the world.

Boserup's pioneering publications have contributed significantly to our understanding of how economic policies and processes affect people's well-being and agency – all people, not just the men of the society. While best known for her work on gender and agricultural systems, Boserup also wrote about the 'bazaar and service occupations' (1970) now called the informal sector that has gained much attention with economic restructuring policies since the 1980s (Tinker, 2001). In addition, she wrote on rural–urban migration, polygamy, property rights, education, and urban employment. By demonstrating that women are often marginalized in the course of development rather than gaining from the process, her work helped shift the focus of development research from growth of income toward people's well-being and agency. Boserup argued that better educational opportunities could help reduce the inequality resulting from this marginalization (Turner and Fischer-Kowalski, 2010). Rodgers (2010) notes that Boserup's work has been useful in policy efforts to reduce the gender gap in education, especially in Asia and South America.

Boserup's work is global and interdisciplinary in perspective, addressing the links between culture, environment, technology, population, employment, and family. She framed the argument for women's rights in terms of development that was more acceptable to the mainstream at the time (1999). She brought efficiency as well as equity into the argument for women's rights and a just society, but she did not depict women as victims

(Jaquette, 1990). Boserup used her publications to make women's work visible and stressed the contributions of women as well as men to economic growth.

Boundaries and New Organization Forms

This article is a revision of the previous edition article by W.W. Powell, volume 2, pp. 1295–1298, © 2001, Elsevier Ltd.

Abstract

Organizational boundaries, the demarcation between an organizational entity and its external environment, have undergone considerable remaking in recent years. Long thought to be relatively stable, boundaries were once redrawn only to gain more leverage over external factors or increase scale. But boundaries have become much more fluid and permeable as organizations experimented with a wide variety of new organizational forms to access critical knowledge, skills, and resources. Particularly in knowledge-intensive contexts, there is ample evidence of growth in novel collaborative forms of organizing. In this article, several arguments that offer insight into the creation of novel forms are highlighted, the limits of an atomistic view of organizations are emphasized, and avenues for future research are offered.

Introduction

New systems of organizing do not arrive on the scene readymade and announce their availability. The historian David Hounshell (1984) illustrated how the mass production model emerged piecemeal in the United States in the later half of the nineteenth century, beginning with the use of interchangeable parts in rifles. Subsequently, the manufacture of sewing machines and then bicycles, and later, meatpacking and beer brewing all played a critical role in the eventual development of the assembly line by Henry Ford. Similarly, new forms of organizing in the late twentieth century emerged incrementally, in fits and starts, and became visible in a variety of guises. For much of the second half of the twentieth century, arguments from economics and sociology drew on considerations of efficiency and power to stress that organizational boundaries sharply demarcated an organization from its external environment. Indeed, some organizations operated like medieval castles, walled off and protected from external influences. When boundaries were redrawn, considerations of scale and scope loomed large as decisions to shift boundaries were based on weighing the costs of internalizing a transaction versus conducting it in the market (Williamson, 1985). In another line of work, emphasizing the ability of an organization to maintain autonomy and control over its environment, boundaries were recast to either reduce uncertainty or dependency on external parties (Pfeffer and Salancik, 1978) or to reshape the production chain in order to enhance strategic position within an industry. These lines of research were subsequently challenged by a wide proliferation of alternative governance arrangements and new types of organizational forms.

Today, organizations worry more about their adaptability to a changing landscape than their adaptive fit to a specific environment (Smith-Doerr and Powell, 2005; Stark, 2009). These new forms enhance absorptive capacity (Cohen and Levinthal, 1990), that is, the capability to access skills and knowledge located outside the organization, as well as the ability to reconfigure organizational practices and structures to respond to a rapidly changing environment in which internal activities are increasingly interdependent with external parties (Carlile, 2004; Meyer et al., 2005).

The unraveling of the old system of bureaucratic employment in the large firm is now widely recognized, but developing a set of metrics to assess the spread of new forms of work and organizing is challenging. The developments underway are multilevel in nature, involving a transformation in the ordering of work at the point of production, increased porousness of the boundaries of many organizations, and a remaking of relations with competitors and collaborators (Fleming et al., 2007; O'Mahony and Bechky, 2008). These developments are discontinuous because there is no clear stopping point in the process and no road back to the previous system. Performance has replaced seniority as the condition of employment. Learning and speed have replaced quantity as the criteria for evaluating organizations. These shifts bring new actors and new business models to the fore, and push aside incumbents.

New Forms of Workplace Organization

Jobs emerged in the late nineteenth and early twentieth centuries as a way to package work in settings where the same task was done repeatedly. But work has changed into short-term projects often organized around a team or work group charged with responsibility (Hargadon and Bechky, 2006). Consequently, the future organization of work is likely to be much less frequently honeycombed into a pattern of highly specified jobs.

Sabel (1994) terms this process of joint exploration 'learning by monitoring.' The activities of work teams are coordinated by a process of iterated goal setting. General projects, such as the design of a new car, are initially determined by study of best practices and prospects for competing alternatives. Then broad plans are in turn decomposed into tasks for work groups, located inside, outside of, and across organizational boundaries. The goals are subsequently modified as work teams gain experience in executing the required tasks. Through these revisions, changes in the parts lead to modifications in the conception of the whole, and vice versa. The same procedure of monitoring decentralized learning, moreover, allows each party to

observe the performance of the other collaborators closely enough to determine whether continued reliance on them, and dedication of resources to the joint projects, are warranted.

This form of production integrates conception and execution, with design and production running on parallel tracks. With concurrent design and development, participants constantly evaluate each other's work. If project groups decide who supplies their inputs, they need not choose the traditional internal unit, but instead turn to outside suppliers if they provide better value. This reconceptualization of work reduces and exposes fixed costs, making the expenses of all units dependent on their contribution, and fuses the knowledge housed in different parts of the organization and the environment.

These new arrangements are deeply corrosive of the old system of sequential steps, linear design, and vertical integration that provided the worker and manager alike with security. One consequence of this proliferation of collaborative work is the democratization of the product development process at the expense of internal lines of authority (von Hippel, 2005). Another consequence is that important tasks no longer need to be performed inside the organization. This change remakes not only the organization of work but also the boundaries of organizations.

Flattening of Hierarchies and the Spread of Networks

In tandem with a conception of work as organized around projects that transforms firms internally, the growing involvement of organizations in an intricate latticework of collaborations with 'outsiders' also blurs the boundaries of the firm, making it difficult to know where the firm ends and where the market or another firm begins. The former redraws internal lines of authority, while the latter spreads the core activities of the firm across a wider array of participants, with an attendant loss of centralized control. As one of the first astute observers of these developments, Rosenbloom and Spencer (1996) suggested that industrial competition was resembling less a horse race and more a rugby match in which players frequently change uniforms.

Various forms of organizational collaborations have grown rapidly. So intensive are these partnering efforts that the interorganizational network is increasingly the relevant unit of production and the locus of innovation (Powell et al., 1996; Carlile, 2004). Rivalry among single firms has shifted toward networks of allied organizations competing against one another (Gomes-Casseres, 2006). Such alliances do not dampen rivalry, but instead shift the playing field to both competition and collaboration among rival networks with fluid membership.

The growth of alliances entails complex collaborations with suppliers, end users, distributors, and even competitors, ranging from informal ties to formally defined partnerships. This upsurge in collaboration is particularly striking in knowledge-intensive industries (Heckscher and Adler, 2006). Networks have become an essential component in such contexts because they channel information and resources, and afford rapid organizational learning.

Collaboration in Research and Development

In research and development (R&D)-intensive settings, forms of organizing for technological innovation have undergone a significant transformation. Among the many challenges of the early twenty-first century are much shorter product development cycles, more sophisticated technological infrastructures, geographically distributed knowledge, and pressing global issues such as climate change. These challenges have provoked deep changes in the organizational structure of R&D. The once prevalent form of centralized in-house R&D has vanished, while the boundaries of organizations have become less fixed and more open-ended as the development of novel products and services requires greater coordination across various types of organizations (Lingo and O'Mahony, 2010). The wellspring for new ideas is no longer the individual firm; the generation of novelty takes place at the nexus of different kinds of organizations.

Collaboration has also notably increased with organizations in the public sphere, such as universities, nonprofit organizations, and governmental agencies. With this upsurge, organizational 'castles' with clear boundaries, strong fences, and protection from outside forces have been superseded by numerous types of partnerships and affiliations. Formerly canonical decisions, such as make or buy or centralized versus decentralized R&D, are inadequate in a high-velocity environment. As more types of alliances appear, organizational boundaries become more fluid and porous, which poses very different questions and challenges for both contemporary corporations and scholars.

In recent decades, teaming up with competitors has become a frequent form of organizing. Particularly in fast-paced industries, linkages among direct competitors – also coined coopetition – offers access to valuable resources and knowledge for established and young firms alike (Bengtsson and Kock, 2000). Competitors typically hold highly relevant knowledge and complementary resources. Such interfirm arrangements therefore often lead to enhanced reciprocal learning and higher levels of absorptive capacity (Cohen and Levinthal, 1990). Partnerships open up access to new ideas, opportunities, critical information, and an expanding array of informal contacts. Such relationships can take various forms, ranging from strategic alliances and joint ventures to less formally defined partnerships.

Collaborative arrangements with suppliers and subcontractors have gained prominence along every stage in the value chain. In vertical interfirm linkages, corporations typically engage in the exchange of specific resources and services rather than the pooling of complementary assets. Relying on subcontractors or external suppliers reflects an effort to reshape the contours of production by substituting outside procurement for in-house production. Suppliers and subcontractors work under short time frames, provide considerable variety of designs, spend more on R&D, and deliver higher quality, while the 'lead' firm affords relation-specific investments and reciprocal access through data sharing and security through longer term relationships. Procurement relationships are no longer just a source of high quality and critical components, but generate mutual benefits including reduced uncertainty and performance advantages (Dyer, 2000).

Among the broad array of collaborators are also customers and consumers of the product or service under development. Co-creating with end users and entire user communities enables firms to tap sources of new ideas and opportunities, develop applications with immediate commercial potential, and enhance their position in an emerging technological field (von Hippel, 2005). User–firm arrangements have become particularly visible in the production of software. As opposed to the closed model of R&D in which firms protect their prototypes from outsiders, these forms of organizing pursue development in an open manner (Chesbrough, 2005). In such settings, knowledge gains stem from diverse contributors of a community and potential buyers of a product.

Public and nonprofit organizations also increasingly redefine their boundaries. Growing linkages among public, private, and for-profit entities lead to the rise of hybrid structures. Such public–private 'hybrids' have formed at the crossroads of the academy and commerce, between business firms and nonprofit organizations, and with the government (e.g., Murray, 2010; Jay, 2013). The various collaborative arrangements in which external partners take an active role reshape organizational boundaries, making them more porous and requiring new skills to manage.

Ramifications

Technological progress today takes place at the nexus of various kinds of organizations. These interstices between organizations are the locus where knowledge is generated and new products and services developed. But such fluidity and porousness poses challenges for managers and scholars alike. How can organizational boundaries be analyzed if they are in flux? If there is no natural stopping point in the chain of decisions to devolve centralized control, fixing the boundaries of an organization becomes a daunting task, as relationships with suppliers, subcontractors, customers, and competitors evolve in unexpected ways. When network ties proliferate and deepen, it becomes more sensible to exercise voice rather than exit. A mutual orientation between parties may be established, based on knowledge that the parties assume each has about the other and upon which they draw in communication and problem solving. Fixed contracts are thus ineffectual, as expectations, rather than being frozen, change as circumstances dictate. At the core, then, of this form of relational contracting are the entangling strings of reputation, interdependence, and learning.

Much sophisticated technical knowledge is tacit in character – an indissoluble mix of design, process, and expertise. Such information is not easily transferred by license or purchase. Moreover, passive recipients of new knowledge are less likely to appreciate fully its value or be able to respond rapidly. Learning is closely linked to the conditions under which knowledge is gained (Powell et al., 1996; Brown and Duguid, 2002). Thus, regardless of whether collaboration is driven by calculative motives, such as filling in missing pieces of the value chain; by strategic considerations to gain access to new knowledge; or by prior social relations, network ties become admission tickets to high-velocity races. Connectivity to an interorganizational network and competence at managing various types of partnerships have become key drivers of this new logic of organizing.

Motives and goals for the formation of such linkages are as varied as the forms they take. The growth of collaborative linkages is driven by divergent factors and pursued in a different manner by a wide array of organizations. Larger organizations are making their boundaries more permeable in order to procure key components or critical R&D. Subcontracting and outsourcing are steps taken to reduce fixed overheads. Organizations cooperate with competitors and users in order to take on projects too risky or complex for one entity to pursue alone. Clusters of small organizations collaborate, and so do public and private organizations, cohering into a network to create what no single entity could on its own. In sum, organizations are coming to resemble a network of treaties because these multifaceted relationships encourage learning from a broad array of collaborators and promote experimentation with new forms of organizing, while at the same time reducing the cost of expensive commitments. One tangible outcome of these network initiatives is enhanced technological innovation.

Novelty and Multiple Networks

Clearly, innovation is increasingly likely to occur at the crossroads of various types of organizations, but explaining when and how this occurs is undertheorized. A conceptual framework offered by Padgett and Powell (2012), which sheds light on how organizational novelty arises, takes shape, and persists, combines research on multiple social networks with the biochemical literature on the origins of life, using the concept of autocatalysis. New organizational forms do not rise like a phoenix. The mechanisms out of which new genres develop and evolve are fundamentally relational and dynamic. At the intersection of multiple, interlinked social networks, ideas and practices are transposed across multiple social worlds and repurposed for new uses.

Organizational forms can be conceived of as assemblages of elements and practices. For newness to occur, existing templates and ideas must flow together and be recombined in novel ways, and integrated into the social world. Although individual skills and competencies are certainly important ingredients in this process, innovation is most often the result of collective experimentation. Such generative dynamics frequently occur when otherwise distant social arenas are brought together. Structural spaces between multiple networks have a high potential for foreign material and elements to flow together and become repurposed and rearranged to form a fresh constellation. Multiple networks are linked when people and organizations, either stemming from diverse domains or simultaneously occupying different roles in distinct networks, begin to interact. These intensified interactions can spur coordination and feedback across networks and may result in creative outcomes. Such interactions can take place in more formal spaces, in occasional in situ gatherings, or may be prompted by necessity or serendipity.

Other structural conditions that catalyze multiple networks involve the presence of brokers (Fleming et al., 2007; Lingo and O'Mahony, 2010), influential multivocal leaders (Padgett and Ansell, 1993), and open elites (Powell et al., 2005). These individuals and organizations facilitate the flow of ideas, and

strengthen interaction and interdependencies across realms. Brokers can be effective in connecting otherwise detached parties and social worlds, serving to transfer the creative integration of distant ideas. Multivocal actors utilize language and symbols that appeal to members of diverse networks. Open elites spur novel connections by sponsoring newcomers to join networks. The establishment of such diverse new linkages accelerates the spread of practices and promotes innovation.

The genesis of novel forms and approaches is seldom anticipated. Emerging forms can be either incremental in nature or disruptive with profound ramifications. A contrast that illuminates these differential effects is between innovation and invention (Padgett and Powell, 2012). Innovations improve on existing ways of doing things, whereas inventions change the ways things are done. Thus, when organizational inventions occur, they can have transformative effects on the interlinked social context and alter social boundaries. In contrast, most organizational innovations do not have such wide-ranging effects. But when new forms of organizing alter the social context, and reverberate back and have systemic repercussions for the social networks that originally produced them, significant organizational change occurs.

As one example, the transposition of entrepreneurship into the domain of the university – the emergence of academic entrepreneurship – was initially contested, but subsequently had profound ramifications as commercial engagement became integrated into the academic realm. The novel constellation of commercializing university research had even more systemic effects as it spread into the interconnected domains of the university, industry, and government. The growing role of entrepreneurship in academia spurred new university careers as scientific entrepreneurs became rewarded and encouraged, which fostered industry–university collaborations with academics on industry advisory boards and industry-sponsored research. With the spread of university–industry interfaces, a new organizational regime of proprietary science took root in academia, a social context in which ownership of one's research findings was previously considered illegitimate (Murray, 2010; Colyvas and Maroulis, 2012).

Similarly, community principles such as collective production and voluntarism have been repurposed into commercial settings, promoting open collaboration in the commercial software development domain (O'Mahony and Lakhani, 2011). Previously the home of hackers and hobbyists, community forms such as open source software gained acceptance in the commercial world and in the eyes of governments. The growth of community forms also thrived beyond software and reshaped many existing configurations in the public and private sectors. Prime examples range from voluntary online communities such as Wikipedia and crowdsourcing platforms, to increasingly popular forms of shared consumption including cars and accommodations, to the upsurge of worldwide accessible online learning platforms spreading across universities.

Conclusion

The examination of organizational boundaries was long dominated by efficiency and power considerations (Pfeffer and Salancik, 1978; Williamson, 1985). These approaches led to an atomistic conception of organizations, with research efforts to clearly demarcate one organization from another, and from its environment (Santos and Eisenhardt, 2005). In a more complex and interconnected world, the image of organizations as either dyads or at the center of an ego-centered network neglects the upsurge of collaborations in organizational life, and the interconnectedness of social and economic life in general. Studying organizations as independent in their boundary decisions and detached from multiple relational influences has become inadequate.

The authors encourage future research to systematically examine the social processes out of which novel forms and collaborations arise and are sustained. What are the places where members from distinct domains meet and interact? What structural conditions foster the coevolution of multiple networks? Conceptual as well as empirical work is needed that highlights antecedent conditions that both constrain and enable novel constellations. Work in this area could adopt a multilevel approach to explore both macro- and microlevel attributes affecting the formation and coevolution of interconnected social arenas. There is also profound need for research that focuses on organizational failures and attempts that do not come to fruition. Such work could significantly contribute to our understanding of the social mechanisms and structural forces that defer or impede organizational innovation. Another promising line of investigation examines the role of boundary work and boundary organizations in enabling collaborations across distinct social arenas (O'Mahony and Bechky, 2008). Research focused on the intersection of boundaries and multiple social networks will afford insight into the shifts taking place in the nature and position of boundaries in today's interconnected organizational landscape.

Bounded Rationality

Abstract

The research program of bounded rationality is built on three premises: (1) humans are cognitively constrained; (2) these constraints impact decision making; and (3) difficult problems reveal the constraints and highlight their significance. Thus, strategies may be optimal in easy domains (e.g., tic-tac-toe) but suboptimal in hard ones (e.g., chess). Understanding the most important mental constraints, such as selective attention and limited working memory, helps explain why people use certain kinds of heuristics (i.e., rules of thumb) in hard domains, hence why and how performance is suboptimal. However, the Simonian branch of this research program emphasizes why many highly trained specialists manage to perform *relatively* well despite working under these universal cognitive limitations. By contrast, the Tversky–Kahneman branch focuses more on errors made by everyone, experts and novices alike. Theories of bounded rationality have been applied to diverse political contexts such as elections and budgeting; these models are briefly described.

Introduction

The central ideas of bounded rationality (BR) are straightforward. First, humans are cognitively constrained in various ways, e.g., we can consciously attend to only one choice problem at a time. Second, these mental properties have behavioral consequences: they significantly affect decision-making. Third, the harder the problem the more likely it is that a decision-maker's information-processing constraints will matter (Simon, 1981).

The first claim is uncontroversial. Cognitive psychologists have demonstrated, for example, that our short-term or 'working' memory holds only a few (between about five and nine) chunks of information (Miller, 1956). The second claim follows close on the heels of the first. Since our working memory is small, our conscious attention must be selective. Hence, e.g., an agency head can work on only one problem at a time, no matter how many his subordinates present to him.

The third claim is important for demarcating domains in which BR theories have empirical 'bite', i.e., their predictions differ from those of other theories – especially those of BR's main competitor, rational choice (RC) theories. Consider Simon's formulation: "the capacity of the human mind for formulating and solving complex problems is very small compared with the size of the problems whose solution is required for objectively rational behavior in the real world – or even for a reasonable approximation to such objective rationality" (1957, p. 198). Thus, bounded rationality describes a relation between a person's mental abilities and the complexity of the problem he or she faces. It is not a claim about the brilliance or stupidity of human beings, independent of their task environments. It is easy to miss this central point and to reify the idea of bounded rationality into an assertion about our absolute capacities (e.g.,'people are dumb'). The fundamental notion is of cognitive limits, and as is true of any constraint, if cognitive constraints do not bind in a particular situation, then they do not matter: they will not affect the outcome. And whether they bind depends partly on the demands placed on decision-makers by the problem at hand. Simon has called the joint effects of "the structure of task environments and the computational capabilities of the actor … a scissors [with] two blades" (1990, p. 7). Theories of bounded rationality have cutting power – especially relative to RC theories – only when both blades operate.

Since this is the program's foundation, it is worthwhile exploring its implications via an example. Consider a group of normal adults, randomly paired up to play either chess or tic-tac-toe. A pair can either play their assigned game or they can stipulate a particular outcome, take their money for participating in the experiment and leave. The intuitive prediction is that more people assigned to tic-tac-toe would stipulate an outcome (a draw): after all, that game is trivial.

However, so – in a sense – is chess: Zermelo proved long ago that there exists an optimal way to play chess, and if played optimally then, as in tic-tac-toe, the same outcome always occurs: either white wins or black does or they draw. Indeed, for classical game theory, which ignores cognitive constraints, chess and tic-tac-toe belong to the same class: they are zero-sum, finite games of perfect information. Hence they are game theoretically equivalent. In the real world, of course, these games are not equivalent. Normal adults do not play tic-tac-toe; it is pointless. But they do play chess; indeed, for some it is a career. The point is simple but vital: our mental abilities are a binding constraint in chess but not in tic-tac-toe. Accordingly, BR and RC theories make observationally equivalent predictions about the latter but not the former. Hence BR theories have cutting power in chess – knowing the players' cognitive capacities gives us predictive leverage – but not in tic-tac-toe.

The example provides a more subtle point. Chess simplifies toward a game's end, but the players' cognitive capacities remain the same. Since the task's demands are falling while mental resources stay fixed, at some point *those resources may no longer be a binding constraint*. If that happens, the players will play optimally, and so a standard RC theory will accurately predict their behavior from that point on: a chess master burdened by a big disadvantage in the endgame will resign, for he knows it is hopeless. Once the players can identify the optimal strategies, the game becomes completely predictable, hence continuing is as pointless as playing tic-tac-toe.

This example reveals the subtlety of the contest between BR and RC theories. Theories from these two research programs predict different behaviors in chess only when the game is sufficiently complex so as to make players' mental capacities binding constraints. For expert players, this condition holds early in the game but not at the end. Thus, the two types of theories make observationally equivalent predictions about the endgame behavior of experts.

The lesson is that the theoretical significance of bounded rationality turns on the *difference* between cognitive resources and task demands, not on the former's absolute level.

The Main Branches in Political Science of BR

Bounded rationality should not be confused with a theory (e.g., of satisficing), much less with a specific formal model (e.g., Simon, 1957). It is best considered a research program: a sequence of theories with overlapping sets of assumptions, aimed at solving similar problems. Political scientists have often conflated BR with the specific theory of satisficing, but that conflation produces a serious underestimation of the program's substantive content. In principle, the program's empirical domain is vast – it is as imperialistic as the rational choice program – and so its set of possible theories is also very large.

Many research programs contain multiple branches. So it is for BR: political science alone exhibits two main orientations toward bounded rationality. The first orientation sees the glass as half full, emphasizing how people manage to do 'reasonably well' *despite* cognitive limitations, *even in complex tasks*. Here belong Simon's line of work and also Lindblom's theory of incrementalism (Lindblom, 1959; Braybrooke and Lindblom, 1963; Bendor, 1995). In the second branch, the glass is half empty: it emphasizes how people make mistakes *even in simple tasks*. Here is the Tversky–Kahneman (T–K) research tradition on heuristics and biases. (For a superb overview see Davis et al., 1966.)

The Glass Is Half Full

As noted above, one of Simon's key premises is that a decision maker's 'inner environment' (Simon, 1981) of information processing will become manifest only when the task is sufficiently difficult. This implies that in order to discover the important types of mental limits, one should study people facing hard problems, such as chess.

But analyzing chess revealed more than mental limits: it generated new questions for the Simonian line, especially about performance. People's performance in chess varies tremendously, and this variation demanded an explanation. Thus, a new research focus emerged: how do some decision-makers *do so well*, given that they face similar cognitive constraints? Thus, scholars in this branch came to see the glass as half full: on some hard problems some humans perform very well, relative to an empirically sensible aspiration level. Given that objectively optimal play in chess-like problems is clearly impossible, what is interesting is not whether people behave fully rationally – we know they don't – but how do relatively competent agents work around their cognitive limits. (See, e.g., Simon, 1990, and the associated references.)

The Glass Is Half Empty

In sharp contrast to the Simonian program's focus on 'good' performance in difficult domains, the prototypical experiment of the T–K tradition shows that even highly trained subjects answering simple questions can perform suboptimally. Kahneman and Tversky's goal – clearly stated in their seminal paper (Tversky and Kahneman, 1974, p. 1124) – was to map subtle mental processes that can cause cognitive illusions, similar to the study of perceptual illusions. This project's results are more striking if they are shown to occur even in simple tasks, just as perceptual illusions are more striking if demonstrated with simple stimuli. The results are still more striking if one shows that even experts are vulnerable to illusions.

Subsequently, however, the field has tended to emphasize more the errors themselves, rather than the underlying cognitive mechanisms: "The … approach triggered an explosion of research on inferential error, and the list of illusions, foibles, flops, and bloopers to which ordinary people were apparently prone became rather long … soon, if there was a mistake to be made, someone was making it in the presence of a social psychologist" (Gilbert, 1998). (After reading many of these studies, the glass probably does look half empty – or worse.) This focus on mistakes triggered a scholarly backlash which has tried to show that humans are better decision makers than the T–K program apparently claims (e.g., Gigerenzer, 1991; for a reply see Kahneman and Tversky, 1996). Unfortunately, this debate has clouded Tversky and Kahneman's original intention, which was not to show that *Homo sapiens* are dolts but rather to uncover fundamental cognitive mechanisms that leave their imprint nearly everywhere. Given the primary objective of demonstrating that certain mental processes are ubiquitous, T–K's approach made sense. But it had the unfortunate side effect of making the program largely inattentive to variations in performance. With a few exceptions (e.g., the study of how people calibrate subjective probabilities), specialists in the T–K branch have shown little interest in performance variation; in particular, genuinely expert performance, at the level of chess masters, has been neglected. Instead, performance evaluations in this branch mostly use dichotomous theoretical standards: do people make choices in accordance with the axioms of expected utility theory? Do they revise beliefs in a Bayesian manner? The answers – generally no, they don't – are less informative than would be answers based on a quantitative scale measuring degrees of sophistication, even if the empirical best was far short of the theoretical ideal.

However, these differences in how the branches' study performance reveal that in one respect the T–K research agenda is more ambitious: it is harder demonstrating that cognitive limits show through on simple problems than on hard ones. Thus, the T–K program has worked on *pushing out the boundaries of BR* by showing that even quite subtle problem representations ('framing') can induce suboptimal performance. (Establishing which problem-representations are transparent – i.e., cognitively obvious – and which are opaque has been important throughout the T–K program (Kahneman and Tversky, 1996).) One needn't go all the way to chess to uncover our mental limitations: humans are sufficiently sensitive (hence vulnerable) to framing so that judgmental or

decisional imperfections appear even when a task exhibits no combinatorial explosion. Thus, a main finding of the T–K program is that BR has predictive bite in a larger domain than once thought.

Essential Properties of Humans as Information-Processors

What are our essential properties as information-processors? Synthesizing Hogarth (1987) and Simon (1990) gives us the following list.

1. Selective perception of information: our objective environments always contain far more information than we can perceive or attend to. Thus, perceptions must be guided by anticipations and other forms of top-down processing (e.g., schemas).
2. High order information-processing, especially conscious thinking and attention, is largely serial. This has significant implications for the real-time behavior of busy officials.
3. Compared with modern computers, humans process many kinds of information slowly, partly due to physiological limits (neurons are much slower than electronic circuits).
4. Compared with computers, people are poor at calculation.
5. Memory is actively reconstructive, not photographic. It therefore lacks photographic fidelity.
6. Although there is no known limit to long-term memory, working memory is very small (Miller, 1956). Thus, because everything that enters the former goes through the latter, short-term memory is a key bottleneck in information-processing.

The other crucial type of cognitive property are ways in which humans work around the above constraints. Simon calls these mechanisms for procedural rationality (1981; 1990). Three are especially worth noting.

1. Recognition processes. After long experience, experts have stored a great many patterns about their tasks in long-term memory, both about situations ('this is situation type x') and actions ('in situation x, do y'). For familiar problems a fundamental trick is to *substitute recognition for search*.
2. Heuristic search. When recognition fails, experienced decision-makers fall back on search. For reasonably complex problems search is heuristic: optimality is not guaranteed. Instead, heuristics make complicated problems manageable: they cut them down to (human) size and, in the hands of experts, often yield 'good' solutions. There are two types of heuristics. If the task is highly and recognizably structured, experts will use powerful task-specific heuristics. When these are unavailable they use general (but weak) heuristics such as satisficing (stop searching for alternatives when you find one that satisfices – exceeds your aspiration level – rather than requiring an optimal solution). Note the place of satisficing here. Far from being the heart of BR, it is merely one of several general-but-weak heuristics.
3. Heuristic search occurs in *problem spaces*: mental representations of the task at hand. Experts learn to use economical and sometimes powerful problem representations.

Applications: Theories of Politics

Budgeting

Building on Lindblom, Wildavsky and his colleagues constructed an incremental model of budgeting (Davis et al., 1966) which received substantial empirical support. Crecine (1969) argued that the general heuristic of decomposition – when faced with a hard problem, decompose it into smaller, easier subproblems (Simon, 1981) – is central to budgeting, and developed a model of city budgeting based on that idea. Padgett (1980) created a model of federal budgeting that continued to use the BR notion of heuristic search but which implied that allocations will sometimes be nonincremental.

Organizational Reliability

Landau (1969) has shown that certain types of structural redundancy can make organizations more reliable than any of their subunits. (Consider several R&D teams working in parallel.) Relatedly, Ladha (1992) and others have shown how using Condorcet's jury theorem can reduce both type 1 errors (e.g., the Food and Drug Administration's approving bad drugs) and type 2 errors (rejecting good drugs). Significantly, these results hold even if individual decision-makers face quite severe cognitive constraints.

The Evolution of Cooperation

Axelrod (1981) and Bendor and Swistak (1997) have used evolutionary game theory to analyze how cooperation might emerge and stabilize when central authority cannot solve Hobbes' problem. (Evolutionary game theory assumes that people learn to use strategies that work and to discard those that fail; agents need not optimize.)

Subgovernments

Bendor and Moe (1985) constructed a model of subgovernments with myopic actors (legislators, an agency and interest groups). The simulation outcomes were typically 'pluralist equilibria,' characterized by a balance of power between the interest groups.

Electoral Competition

In Kollman et al. (1992), adaptively rational political parties compete for the support of voters in two-party elections. In unidimensional policy spaces the parties converge to the median voter (Pages, personal communication, September 1999); this result appears to hold for a wide variety of search heuristics. Hence Downs' famous result can be derived with weak cognitive assumptions. In a multidimensional policy space, the parties behave 'sensibly' but can get hung up on local optima. This suboptimization depends crucially on nonobvious aspects of voters' preferences.

Prospect Theory

The key premise of prospect theory, Tversky and Kahneman's most important theoretical contribution, is that choices are

evaluated relative to a reference point, e.g., the status quo. The second assumption is that people are risk-averse about gains (relative to the reference point) but risk-seeking about losses. The third premise is loss-aversion: losing x hurts more than gaining x helps. This simple and elegant structure has yielded suprisingly powerful predictions in the study of bargaining (Neale and Bazerman, 1991), international politics (Levy, 1997), and voting (Quattrone and Tversky, 1988).

For an excellent and accessible review of the BR program in economics see Conlisk (1996). Rubinstein (1998) is very instructive but much more technical.

Editor's Note

The research program on "bounded" or "limited" rationality continues in both political science and behavioral economics. For an update of bounded rationality thinking in the latter, see Camerer et al., 2004. Within the discipline of political science, readers will find the following of interest: Poulsen, 2014; Ostrom, 2012; Vollaard and Martinsen, 2014; Botterill and Hindmoor, 2012; Binswangera and Prüfer, 2012; Bendor, 2003.

Abstract

One of the most important thinkers of the second half of the twentieth century, French sociologist Pierre Bourdieu (1930–2002) developed a theory of social domination and reproduction based on the concepts of 'habitus', 'capital' (economic, cultural, social), 'field', and 'symbolic violence'. This theoretical framework is rooted in extensive empirical research in the sociologies of education, culture, work, and social stratification. He also dealt with gender, political sociology, and economic sociology. Following the evolution of his thought and career, the article presents his theory of practice, social classes, field, and symbolic violence, ending with his engagement as a public intellectual.

Bourdieu's theory of the social world combines a structural approach to power relations with a historical perspective on reproduction and change. It provides an original synthesis of the classical theories of Marx, Durkheim, and Weber, while striving to overcome the traditional oppositions between structure and individuals, objectivism and subjectivism, continuity and discontinuity. Agents are determined by the class and gender conditions in which they were socialized (habitus), but still have latitude to maneuver in different situations according to their dispositions and the various types of capital (economic, cultural, social) they are endowed with. Their actions and strategies are oriented by the rules and values of the fields in which they occur and by the position they occupy in these fields. Contrary to rational action theory, Bourdieu's theory of action distinguishes between different kinds of interests with regard to the "illusio", the belief in the issues at stake in the field (political, economic, legal, professional, artistic, literary, and so on). The focus on belief allows him to highlight the symbolic aspects of domination and the mechanism of symbolic violence.

From Philosophy to Anthropology: The Theory of Practice and the Concept of Habitus

Pierre Bourdieu was born on 1 August 1930, in Denguin, France, (Pyrénées-Atlantiques department) to a father who was first a farmer, then a postman, and then a postmaster, and a post office employee mother. He attended the Lycée de Pau before becoming a student at Lycée Louis-le-Grand in Paris, from which he entered the prestigious École normale supérieure on the Rue d'Ulm in 1951. In 1954, he obtained the philosophy *agrégation* (a competitive certificate providing access to high school teaching positions) and became a teacher at the Lycée de Moulins. In 1955, in the middle of the war for Algerian independence, Bourdieu was called to military duty in Algeria. His research on Algerian society began at this point. Partway between Orientalism and ethnology, it resulted first in a small book entitled *Sociologie de l'Algérie*, which was published in 1958, the same year he was named as Assistant Professor at the University of Algiers. In order to understand the transition from precapitalist societies to capitalist economies, he then conducted three studies: the first, carried out in 1958, dealt with traditional Kabyle society; the second (1960) with Algerian workers in urban spaces (*Travail et travailleurs en Algérie*, 1963; *Algérie 60*, 1977a); and the third, also from 1960, dealt with regrouping centers and the effects of colonialism more generally (*Le Déracinement*, 1964, with Abdelmalek Sayad).

Together with a study on celibacy in the sociologist's native province of Béarn, which he undertook upon his return to France in 1960, these studies form the basis for Bourdieu's theory of practice and habitus (*Esquisse d'une théorie de la pratique*, 1972; *Le Sens pratique*, 1980). The theory was born out of a confrontation with Lévi-Strauss' structural anthropology and draws from Bourdieu's reading of Merleau-Ponty, Husserl, Heidegger, Weber, and Wittgenstein. His reflection on the concept of practice has its roots in a double critique of subjectivism and objectivism. On the one hand, from Sartre's conception of freedom to rational choice theory, subjectivist approaches assume that action is produced by the will of a conscious subject, capable of projecting herself into the future and anticipating the consequences of her actions, both of which are assumptions Bourdieu rejected. On the other hand, structuralist objectivism turns agents into quasi-mechanical conveyors for structures. The polysemic use of the notion of the rule in structural anthropology, at times appearing as a norm that agents follow consciously, and at other times as a principle reconstructed by the researcher in order to account for the regularity of practices, alerted Bourdieu to the breaches and biases of this approach, and he criticized its intellectualist bias (he later termed it a 'scholastic bias'). Moreover, the inscription in time of exchanges such as the gift and the counter-gift, or the challenge and the counterattack, renders insufficient any mechanistic explanation of the logic governing these interactions. The theory of practice emphasizes the specificity of the logic of practice, which is carried out in particular situations, and often with immediacy, as opposed to the time and reflexivity that characterize scholarly activity.

Scholarly reason fails to account for practice because, as Marx said, it takes the things of logic for the logic of things. However, the logic of practice is radically different from logic: it is a fuzzy logic that evades attempts to apply systematically the structural method in order to reconstruct the system of cultural oppositions, because of the ambiguous signification of certain

elements that may vary according to the principles of oppositions they refer to, meaning that there is no perfect structural homology between these different principles; Bourdieu observed this with Kabyle ritual practices. The practical sense ('sens pratique') is at once a sense of orientation and a sense of the game: that is what makes it possible for agents to adjust to an infinite number of situations without explicitly following norms, rules, or codes (and the mechanistic structural approach cannot explain this), and at the same time without actually obeying that which their thought freely decrees (as subjectivist or rational choice theories would have it).

How is this adjustment possible? The answer to this question lies in two key concepts from Bourdieu's theory of practice: habitus and strategy. Bourdieu began to theorize the concept of habitus in the afterword to his French translation of Panofsky's book, *Architecture gothique et art scolastique* (1968), then took it further in *L'Esquisse d'une théorie de la pratique* (1971), defining it as the schemes of perception, evaluation, and action that individuals internalize during their primary (familial) and secondary (school-based) education in the form of dispositions. These 'structured structures', which frame the agents perception, action, and judgment, underlie the adjustment between subjective perception and the objective structures of the social world. They explain the agents' ability to develop strategies that are more or less adapted to the situations they encounter. The notion of strategy refers to the extent to which the agents are able to improvise according to their dispositions.

Examples of perfect adjustment between strategies and situations represent, however, only one particular case among different possibilities. In his studies on Kabyle society and the peasant society in Béarn, Bourdieu observed the contrary: individuals had difficulty adjusting to new situations in contexts of social transformation, that is, when social structures no longer resembled those they had internalized, and when the value system had changed. Cases such as these reveal the gap between subjective perception and objective structures in a world undergoing change. The inability to adjust to change results from a contradiction between traditional values (such as joint ownership of property, the logic of honor which rejects calculations and rationalizations of economic exchanges, the notion of time) and capitalist logic. The inertia of the past is felt through deeply ingrained habits. Bourdieu's ethnographic description of a ball where celibate males, rooted resolutely in the land, stay grouped together in a corner while country girls dance with boys from the city reveals the demonetization of peasant values in the Béarn. This description of the body of peasants, published in 1962, contains the first appearance of the term habitus in Bourdieu's work. Here it is associated with hexis, referring to Marcel Mauss and his analysis of 'techniques of the body'. But the body is also the site of practice, invention, and improvised behavior, more or less adjusted to given situations. This faculty of improvisation remains nevertheless limited by the conditions of its socialization, that is, by habitus, as incorporated habits often resist – the expression of their inertia – individuals' most conscious attempts to master their bodies.

This theory of practice therefore establishes a general theory of action, ranging from the most ritualized actions to the most inventive (creation, scientific innovation). All the while taking this faculty of improvisation into account, the concept of habitus thereby outlines the limits of free action, in contradistinction to Sartre's philosophy of freedom and Goffman's sociology of roles. The concept of habitus therefore allows Bourdieu to integrate the achievements of different sociological traditions: the Durkheimian tradition of studying forms of classification, especially in its structuralist adaptation, the Marxist tradition, which relates forms of consciousness to conditions of existence, and the Weberian critique of Marxist materialism, which re-establishes the place of social groups' vision of the world in the orientation of their action.

The concept of habitus is also at the heart of the Bourdieuan theory of domination, which relies on 'symbolic power'. Bourdieu's conception of symbolic power is in line with the neo-Kantian rationalist tradition, which holds, against the empiricist tradition, that the vision of the world is structured by categories of perception. In sociology, this tradition is represented by Durkheim and Mauss, and in philosophy, by Cassirer. Bourdieu reminds us, however, following Marx and Weber, that these categories are not neutral, but rather fulfill ideological functions and thus underlie the mechanisms of domination (Bourdieu, 1977a,b). For Bourdieu, symbolic power derives its efficacy from being internalized in bodies, in the form of dispositions that constitute the habitus. Symbolic power is observed, for example, in linguistic exchanges, which result from the encounter between a linguistic habitus and a market that confers meaning upon them (Bourdieu, 1982a,b). Indeed, language is at once a site of expression of common sense, that is, of the schemes of perception and classification instilled in education that underlie 'logical conformism', and the site of separation between social groups, between sacred and profane knowledge. A place of interaction between thought and the body, language is both a medium of communication and the vehicle for the daily exercise of domination via symbolic violence.

Bourdieu's reflection on the symbolic dimension of exchanges and power relations in society originated in his observations of precapitalist societies. In precapitalist economies, where there is no systematic reproduction of the mode of domination, political authority comes from the asymmetry of exchanges, that is, from ostentatious redistribution, but also from an ensemble of strategies oriented toward the domination of people via the mechanisms of symbolic violence (Bourdieu, 1972, 1980). This observation leads the sociologist to a refutation of what he calls 'economism', that is the propensity to reduce exchanges to material interest. Bourdieu contests the relevance of this analysis even in capitalist societies, as he argues later in his book *Les Structures sociales de l'économie* (Bourdieu, 2000a,b). Symbolic capital is credit, broadly speaking, based on a group's belief system. In Kabylie, symbolic capital takes the form of honor, but in capitalistic societies, cultural capital is the paradigmatic embodiment of this symbolic capital, as Bourdieu showed in his studies of contemporary French society.

The Concept of 'Cultural Capital' and the Theory of Social Classes

These studies were undertaken upon Bourdieu's return to France at the Centre de sociologie européenne, founded by Raymond Aron, and of which the young sociologist became co-director in

1964, the year he was hired as a Directeur d'études (equivalent to a full professorship) at the École pratique des hautes études (after having been Maître de conférences in Lille from 1961 to 1964). He pursued these studies at the Centre de sociologie de l'éducation et de la culture, which he and his team founded in 1970, and where he remained director until 1984 (in 1997, the center became the Centre de sociologie européenne, and in 2010, the Centre européen de sociologie et de science politique). The results of these studies were published in the series Bourdieu launched in 1964, and edited until 1992, at Éditions de Minuit, 'le sens commun' (from 1997 on, the series was passed on to the 'Liber' series at Seuil). Results were also published in the interdisciplinary journal *Actes de la recherche en sciences sociales*, founded by Bourdieu in 1976.

Never separating theory and empirical work, Bourdieu argued for a rationalist epistemology that stood at equal distance from naive inductivism and relativistic constructivism: he called for epistemological vigilance at the crucial step of the construction of the object, which depended on well-controlled hypotheses (Bourdieu et al., 2005). For this reason, he considered research as a craft, a practice, that should be transmitted by training, a kind of 'apprenticeship', like in the arts, rather than through theoretical teaching (see Bourdieu and Wacquant, 1992). The epistemology he defended was also critical, since it questioned common sense and doxa.

With the tools of empirical sociology, Bourdieu dealt with 'burning' and current topics such as student social inequalities in the face of culture as higher education underwent 'democratization' (*Les Héritiers*, 1964), new cultural practices such as photography (*Un art moyen*, 1965), and museum visitation patterns at a time when the Culture minister, André Malraux, was implementing a policy that aimed at making culture accessible to all (*L'Amour de l'art*, 1966).

In *Les Héritiers*, co-written with Jean-Claude Passeron, he revived the sociology of education, proposing a more suitable way of calculating a student's chances for academic success. In order to show social inequality at school, it is indeed not enough to calculate the percentage of students enrolled in university according to the socio-professional category of the parents. Rather this enrollment rate must be linked back to the representation of the categories within the population. It then becomes clear that a student's chances of attending university are less than 1% for a child of farm workers, 1.4% for a child of blue-collar workers, and close to 60% for a child of learned professionals and upper-level executives. Why do students from the dominant classes do better at school? First, because the culture taught at school is closer to the culture of the dominant classes. But this is not all. In *La Reproduction* (1970), Bourdieu and Jean-Claude Passeron analyze the arbitrariness of pedagogic action. Indeed, teachers tend to value the least scholastic aptitudes (such as distance from educational culture) as well as the inherited culture of the family, to the detriment of the scholastic education given at school. The unequal power relation is thereby rendered legitimate by the ideology of the 'gift', wherein academic success is explained by innate capacities and personal merit. Contrary to the Marxist conception, which bases class differences on the mere possession of material means of production, Pierre Bourdieu sheds new light on the weight of inherited 'cultural capital' as a condition for academic achievement, which therefore contributes to reproducing the dominant classes. On the eve of May 1968, this research met with a strong echo in circles of students and teachers, who were experiencing a boom in demands for education, and were dealing with the system's incapacity to respond favorably to the expectations it had engendered.

The results of this study of the modes of domination were expanded and generalized in the survey on tastes and lifestyles that is at the core of Bourdieu's major work, *La Distinction* (1979). Dominant classes distinguish themselves from dominated ones in affirming their distance from necessity in their cultural tastes and lifestyles. Cultural capital, and more generally symbolic capital, appears as the mode of legitimization of social domination. Bourdieu's approach is different from the Marxist theory of social class in its analysis of lifestyles that differentiates fractions of classes not just according to the overall amount of capital, but also according to the capital's composition. The empirical study of lifestyles reveals indeed that when revenues are equal, lifestyle (cultural practices, type of expenditures and investments, sport activities) varies depending on the cultural capital the agents own.

Consequently, Bourdieu analyzes the structure of the social space as a chiasm. Dominant classes are set apart from dominated classes by the overall volume of capital they possess. But this hierarchic space is also structured by the type of capital owned. Dominant classes are split into fractions depending on those with predominantly economic and political capital, and those with mostly cultural capital (learned and intellectual professions), who are dominated within the larger 'field of power'. This same principle of differentiation can be found within the dominated classes, mainly between the educated petite bourgeoisie (schoolteachers, librarians, etc.) and the petite bourgeoisie of merchants. This differentiation of the types of capital correlates with differences in habitus between class fractions.

This chiasm is the result of the process of affirmation of cultural capital, which was imposed and made relatively autonomous with the ideology of the meritocracy. The system of direct reproduction, prevalent under the Ancien Régime, where social hierarchy depended on birth and the direct designation of family inheritors (the eldest was the inheritor, the second was destined for priesthood, girls were exchanged between families or sent to the convent, etc.), as well the tradition of father-to-son transmission of trades, was replaced by a system of reproduction with an 'educational component'. Instead of the old feudal nobility, a 'state nobility' emerged, born of a selection process that is meritocratic in appearance, but contributes in reality to legitimizing social reproduction. The social overselection of students in the *grandes écoles* (elite schools) in France, revealed in a study Bourdieu dedicated to the subject, bears witness to this process. The study (Bourdieu, 1989) articulates reflections on the educational system and the field of power.

It was during this same period that Bourdieu theorized the notion of social capital, which was to become a central concept in the sociology of networks during the 1990s (Bourdieu, 1980). He defined social capital as a network of long-lasting relations between persons who know each other and have economic and symbolic exchanges. In order to maintain social capital, the agents who own it must develop strategies. Though related

to economic and cultural capital, social capital is relatively autonomous and can have a multiplier effect.

The Theory of Field

Beginning in the 1970s, in his seminars (Bourdieu, 2013a) and in the articles collected in the volume *Questions de sociologie* (Bourdieu, 1980), Bourdieu developed his theory of field. The process of affirmation of cultural capital corresponds to the historical process of differentiation and specialization of the work of domination, which, as Max Weber analyzed in the case of religion, occurs through the formation of a group of specialists (Bourdieu, 1971a). The same is true in the case of law, which replaces the religious principle in establishing the legitimacy of political authority, and for other spaces of intellectual production – science, literature, art, music – which Bourdieu defines as fields because of their relative autonomy and specific rules of functioning. The fields of cultural production are spaces of competitive struggles over the monopoly of the specific capital related to a particular activity. These struggles occur according to specific rules (for instance, argumentation in the scientific field), and investment in the game supposes a belief in the game – illusio. Like Bourdieu's conception of social classes, his field theory is based on a relational and topographical approach: agents occupy social positions which are objectively defined in relation one to the other, independently of their interactions and subjective perception. Fields are thus structured around two main oppositions, homologous to the structure of social space. The first places the dominant and the dominated in opposition to one another according to the overall volume of specific capital. This opposition often overlaps with the opposition between the old or the 'established', who tend to defend the 'orthodoxy', and the young or the 'newcomers', who try to subvert this 'orthodoxy' and thus appear as heretical. The religious field, especially the Weberian opposition between priest and prophet, is paradigmatic here (Bourdieu, 1971b). The second opposition confronts the defenders of specific capital, guaranteed via peer judgment (autonomy), with those who subject their production to external, economic or ideological criteria (heteronomy). After the intellectual and religious fields (which served as a matrix), Bourdieu began to study the scientific field (Bourdieu 1976, 1997b) and the political field, which he criticized for its functioning and its fencing in through favoring 'professionals' and excluding the 'profane' (Bourdieu, 1971c, 1977c, 1981a,b, 2002b; Wacquant, 2005). These reflections were to make up an entire research program that would spark projects in different disciplines, namely in political science and the sociology of literature, in France and abroad.

In 1981, Bourdieu was elected on a Chair of Sociology at the Collège de France, the country's most prestigious academic institution (his inaugural lesson, which he gave on 23 April 1982, was published as *Leçon sur la leçon*, 1982). Adopting a reflexive approach, he carried out an empirical study on the academic field. He showed that the field is structured generally by the opposition between faculties that dominate in terms of temporal power (law and medicine) and those that are dominated (sciences and humanities), where symbolic capital prevails. In each discipline, however, there is an opposition between a heteronomous pole tending toward accumulating temporal power through the control of reproducing bodies, and an autonomous pole tending toward accumulating symbolic capital. In the book that was born out of this research (*Homo academicus*, 1984), Bourdieu also develops a model of analysis for historical sociology through the study of the 'critical moment' of May 1968, the structural causes of which he attempts to understand. The historic 'event' results from the interaction of independent causal series, which creates a conjuncture, and from the synchronization (or harmonization) of the different fields through their politicization.

Bourdieu's inquiry on Heidegger (1988) illustrates, through a close reading of his work, what he calls the 'field effect', that is, the mechanisms by which ethical and political dispositions are euphemized through philosophical concepts and are embedded within philosophical problems, following the specific rules of the field.

In *Les Règles de l'art* (1992b), Bourdieu systematized his theory of fields, gathering all of the research he had done on the literary field since the 1960s. In the first part, he retraces the historical process by which the literary field gained autonomy in the nineteenth century, with the development of a pole of small-scale circulation based on peer recognition, as opposed to the pole of large-scale circulation, governed by the law of the market and sales figures. In imposing the primacy of symbolic value over commercial value, this small-scale circuit managed to reverse the principles that govern social space and the economic world. Bourdieu speaks of an 'inversed economy'. Instead of the immediate profitability of best-sellers, small-scale production makes bets on long-term recognition, which can lead to 'canonization', that is, the integration of works turned 'classics', into a national and universal heritage, namely through the educational system.

In the second part of the book, Bourdieu lays the foundations of a science of works. The concept of field, he argues, helps to overcome the alternative between an internal analysis of works, as structuralism suggests, and an external analysis that reduces them, as in the Marxist reflection theory, to their conditions of production. For Bourdieu, the science of works requires three operations: (1) an analysis of the position of the literary field within the field of power (its degree of autonomy) and its evolution in different sociohistorical conjunctures; (2) an analysis of the structure of the literary field according to objective relations between the individuals and groups who compete in the field for the acquisition of specific capital; (3) an analysis of the habitus of these individuals and their social trajectories, since the field effect is not exerted mechanically, but rather it is mediatized by the space of possibilities such as agents perceive it according to their dispositions.

This approach may be applied to other fields of cultural production. Bourdieu used it, for example, in his research on Manet, which he began in the 1980s and to which he dedicated his 1998–99 a series of courses at the Collège de France. These courses, as well as the unfinished manuscript or a book written with his wife, Marie-Claire Bourdieu, deal with the conditions under which symbolic revolutions take place (Bourdieu, 2013b). The sociologist reconstructs the academic system, which exerted a monopoly on artistic formation and the art market during Manet's time. The system functioned as a body organized around its reproduction. Painters careers

followed a predefined path: competition for access to the École des Beaux-Arts, apprenticeship in studios, prizes, exhibition of their works at the Salon through a selective process that gave them access to the art market, and, for the very best, State commissions. The academic aesthetic proceeded from this system: it valued technical mastery (perspective, relief, clair-obscur), readability (or the message), reference to history (at the basis of the hierarchy of genres), and the 'finish'. This aesthetic code, backed up by a state monopoly, was to be destroyed by Manet. However, against a heroic, idealistic vision of Manet's revolution, Bourdieu aims to inscribe this symbolic revolution in the social history it results from, without reducing the aesthetic stakes to socioeconomic and political ones. Such a social history combines technical revolutions (such as the invention of tubes of paint, making it possible to paint outdoors) and morphological factors, particularly the growth of a population of artists who had been excluded from the system and who were, with their anti-academic sentiment, to invent a bohemian lifestyle and an alternate, parallel system with societies of artists selling their own works. Manet's dispositions, the different types of capital (economic, cultural, social) he owned, and his 'cleft' habitus, split between the two poles of field of power, economic and cultural, explain the painter's ability to carry out this revolution.

The Theory of Symbolic Violence

Bourdieu's work on education and the academic system of painting are part of a more general reflection on the State and its role in inculcating the categories of thought that underlie social order. This was the theme of his Collège de France courses between 1989 and 1991 (Bourdieu, 2012). Completing Max Weber's definition of the State, Bourdieu defines it not just in terms of the monopoly of legitimate violence, but also by the monopoly of legitimate symbolic violence – and the latter monopoly suffices, since it legitimatizes physical violence. Contrary to the Marxist tradition, which reduced the State to a superstructure, for Bourdieu the State is the space where 'legitimate identities' are produced and justify procedures of inclusion and exclusion. While the monopolization of symbolic violence must be studied within a perspective of historical sociology, focusing on the role of certain social groups such as jurists, one may also observe this violence on an everyday level in ordinary acts such as purchasing a house, as the ethnological approach illustrates. As a place where the 'public' and the 'official' are created, the State is defined moreover by its monopoly on the universal. It has the power to universalize certain practices or characteristics at the expense of others, which are in turn referred to as particularisms, such as provincial accents versus those of the Parisian elite, or culture said to be popular versus legitimate culture sanctioned by the educational system, or qualities said to be feminine versus masculine attributes. In this way, the State produces the taxonomies and hierarchies that are internalized by the individuals it governs, including those who rebel against it. For Bourdieu, however, the State is not an abstraction: he argues in favor of a sociology of institutions and individuals that make up the meta-field of the State.

The concept of symbolic violence aims to overcome the alternative between coercion and consent in order to understand the mechanisms of domination. Symbolic violence functions via three components acting simultaneously: ignorance of the arbitrariness of domination; recognition of this domination as legitimate; internalization of domination by the dominated. This functioning is at work in masculine domination, a subject to which Bourdieu (1998) devoted a book.

Based on his fieldwork in Kabylie, Bourdieu shows that the masculine/feminine opposition is one of the fundamental principles of the world's di-vision, which organizes the mythical-cosmological categories of perception of space and time: high/low, above/below, right/left, outside/inside, discontinuous/continuous, extraordinary/ordinary, event/duration. Underlying these are the main oppositions that organize social life: culture/nature, public/private, active/passive. Far from being the expression of biological differences, masculine and feminine identities are socially constructed identities (gender) instilled in individuals via bodily training. For boys, expressions of virility, honor, and domination are taught; instilled in girls are expressions of femininity, effacement, and submission (discretion, restraint, lowered eyes, making oneself small, etc.). Biological differences serve to justify the sexual division of work that results from these gendered identities. As such, socially constructed identities are naturalized, and cultural arbitrariness takes on natural appearances. In contemporary societies, these identities are reproduced not only by familial education, but also by institutions – first of which are the Church, the State, and School. In posing the exchange of women as the basis for communication between men, Lévi-Strauss obscured the political dimension of this foundational act of social life, in which violence toward women, turned into objects, is institutionalized. This approach makes it possible to overcome the alternative between coercion and consent that often underlies debates on masculine domination. Symbolic violence implies complicit submission on the part of the dominated, which is not the result of a free, voluntary act, but rather results from the internalization of an androcentric world vision. Nothing reveals these mechanisms better than the logic of self-exclusion of women from the public sphere. Access to education and birth control may have given women the means to independence, but the presence of women in the working world has not sufficed to abolish inequality between men and women, an inequality that results by and large from gendered representations. In equal-level positions, women are often less well paid than men. In the same way, though technical progress may have liberated women from some household chores, the emergence of working women has not sufficed to challenge the sexual division of domestic tasks. In an appendix to the book on masculine domination, Bourdieu published a text in support of the gay and lesbian movement, which is part of the sociologist's engagement as a 'public intellectual'

Reflexivity and Engagement: A Global Intellectual

The last part of Bourdieu's life was marked by growing international recognition and political commitment. Until the 1980s, the international reception of Bourdieu's work, though not

insignificant, had remained limited to the sociology of education, the sociology of art and culture (Bourdieu's work sometimes helped these subdisciplines to emerge, for example in the United States) and anthropology (for the theory of practice). The reception of Bourdieu's work became unified after the English translation of *La Distinction*, published by Harvard University Press in 1984. The publication was met with a loud echo, raising Bourdieu to the level of a theoretician of the social world. In the context of globalization, such a reception led Bourdieu to reflect upon the international circulation of ideas and the conditions of comparativism, which requires, he argues, a comparison from system to system of the principles of differentiation of types of capital (Bourdieu, 1994). This comparative approach also stimulates reflexivity with regards to our own societies.

Increasingly solicited during the 1990s, Bourdieu intervened more and more on current issues. In 1993, the same year he received the gold medal from the CNRS, France's main research organization (and he was the first sociologist to receive it), Bourdieu published *La Misère du monde*, a collection of interviews, realized by a team of researchers, that gave voice to those without a right to public speech. The book met with great public success. It established a new mode of collective political intervention based on scientific work, which was fully theorized in 1995, when Bourdieu took a stand in favor of a large social movement in France, and slightly later, upon the creation of the Raisons d'agir collective and the Liber-Raisons d'agir publishing house.

First in the series was Bourdieu's book *Sur la télévision* (1996a), a critique of the media that set down the bases for an analysis of the field of journalism. Translated into 25 languages, the slim volume sparked a violent campaign against the sociologist in France. From 1995 on, Bourdieu rallied against neo-liberalism (Bourdieu, 1998, 2001a, 2010). Relating his political commitments to a more developed scientific reflection, he published *Les Structures sociales de l'économie* (2002) at the same time, a work showing the necessity of articulating economic analysis together with social analysis, and ending with a description of the process of globalization in the economic field. Bourdieu was also concerned with the effects of growing concentration in the publishing industry with the merging-acquisition process, which challenged the autonomy of intellectual life by reinforcing the logics of profitability: this is why he dedicated his last empirical study to the French publishing field (Bourdieu, 1999). Amplified by the wide media reception of *Sur la télévision*, Bourdieu's international notoriety guaranteed that his engagement would have a worldwide impact, turning him into a true 'global intellectual'.

In the tradition of French intellectuals since Voltaire, Zola, Sartre, and Foucault, Bourdieu put his symbolic capital to the service of political causes in the name of universal principles. But unlike Sartre, who embodied the criticized figure of the 'total intellectual', Bourdieu acted as a 'specific intellectual', in Foucault's term, that is, he limited his interventions to his areas of expertise as a sociologist. Furthermore, he went beyond Foucault in forging the notion of the 'collective intellectual', which takes the division of scientific labor into consideration.

Bourdieu's final course at the Collège de France dealt with science (*Science de la science et réflexivité*, 2001d). Is it possible to account sociologically for the way the scientific field functions without tipping over into relativism? This was Bourdieu's guiding question for his reflexive approach to the practice of research. Proposing to study a 'science in the making' (*science se faisant*) instead of a 'ready-made science' (*science toute faite*), Bourdieu saw in the scientific field – and not in individual scholars – the 'subject' of science. By the orchestration of competitive struggles according to specific rules, the scientific field confers upon science its validity, despite the social determinants and power relations that introduce heteronomous factors. Against the drifting of the postmodern relativists, Bourdieu therefore affirmed a 'historicist rationalism' that refused to rely on an enchanted vision of the scientific world. In his final course, he engaged in an exercise of self-analysis, attempting to explain from a sociological point of view his own trajectory based on his 'cleft habitus' He intended to develop this reflection in a book, but was not able to bring it to term before his premature death on 23 January 2002; the unfinished version was published under the title *Esquisse pour une autoanalyse* (2004). Since his death, the interest in his theory and research program has increased in the world, and he has already become a classical author.

Abstract

The history of the bourgeoisie and the middle classes concerns the development and the transformation of social formations that are made up of those occupying intermediary social positions. These social formations and their members take on mediating or leading functions in society, economics, politics, and culture. The historiography of the bourgeoisie and middle classes takes as its point of departure the development of the modern bourgeoisie out of the older urban bourgeoisie (burghers) of Europe. It concentrates on Western and Central Europe and on the USA, the history of which has, from the eighteenth through the twentieth centuries, been shaped to a large degree by the bourgeoisie and the middle classes. It asks how the functions and meaning of the 'bourgeoisie' and the 'middle classes' have changed in these core areas, how, since the late nineteenth century, the conception has diffused to the periphery of Europe and worldwide, and how, in the process, it has transformed and run up against certain limits. Finally, it analyses the attempts to eliminate or transform the bourgeoisie in socialist countries, and the reconstruction of modern middle classes in postsocialist societies.

Introduction

The history of the bourgeoisie and the middle classes concerns the development and the transformation of social formations that are made up of those occupying intermediary social positions. These social formations and their members take on mediating or leading functions in society, economics, politics, and culture. The historiography of the bourgeoisie and middle classes takes as its point of departure the development of the modern bourgeoisie out of the older urban bourgeoisie (burghers) of Europe. It concentrates on Western and Central Europe and on the USA, the history of which has, from the eighteenth through the twentieth centuries, been shaped to a large degree by the bourgeoisie and the middle classes (Kocka 1995a,b, Zunz et al., 2001). It asks how the functions and meaning of the 'bourgeoisie' and the 'middle classes' have changed in these core areas, how, since the late nineteenth century, the conception has diffused to the periphery of Europe and worldwide, and how, in the process, it has transformed and run up against certain limits. Finally, it analyzes the attempts to eliminate or transform the bourgeoisie in socialist countries and the reconstruction of modern middle classes in post socialist societies (Hoepken and Sundhaussen, 1998).

Historical research on the middle classes investigates symbolic and social structures of long duration, historical continuities and ruptures, and regional and national similarities and differences. Of special interest are the particular characteristics of different formations and actors in various historical contexts. Research topics include the social, economic, professional, political, cultural, and legal characteristics and structures of the middle strata, whether in hierarchically differentiated societies, under conditions of social and cultural inequality, or in processes of class formation. Historians are also concerned with symbolically mediated practices and processes, in which individuals and groups come together in historically identifiable middle classes such as the traditional 'middle estates,' the exclusive 'modern bourgeoisie,' the economic and political 'bourgeoisie,' and the 'broad and inclusive middle classes.' Common to both historical and systematic concepts of the bourgeoisie and the middle classes, however diverse they are otherwise, is the preoccupation with the central region of the society in question, that is with that which takes shape between the extremities. The fundamental assumption is that society is formed and integrated not 'from above' (aristocracy, upper class, oligarchy), or 'from below' (working class, the propertyless, the uneducated), or 'from outside' (foreign domination).

Definitions

The concepts 'bourgeoisie,' 'middle class,' 'middle classes,' and many similar terms applying to particular eras and cultures, have more or less in common, depending on the historical period, the society in question, and the historical situation. A typical characteristic of the historical scholarship on these topics is the tension between exclusive and inclusive concepts of the bourgeoisie and the middle classes.

Definitions vary with regard to the composition of the bourgeoisie, the criteria for inclusion and exclusion, the social and symbolic processes of integration and delimitation, and with regard to the functions and aspirations of the middle classes in society and history. In the fields of social and economic history, scholars may employ classifications that are descriptive, historically and culturally specific, and statistical; or they may, for heuristic purposes, adopt abstract definitions, which are derived from particular theories of the bourgeoisie or from general theories of society. In either case, the focus is on the correspondence between social position and interests. In contrast, cultural historians and culturally oriented social historians understand the bourgeoisie and the middle classes primarily in terms of images of self and other, strategies, performances, discourses, rituals, institutions, sociocultural practices, habitus, and mentalities. In the history of ideas and of philosophy, as well as in theories of the state, law, and constitutions, scholars usually rely on normative and systematized conceptions of the bourgeoisie and middle classes. Social historians also draw on *Begriffsgeschichte*, the history of

ideas, and the history of mentalities in order to show how, under what conditions, and why the concepts 'middle class,' 'bourgeoisie,' and 'middle classes' have been employed for the self-definition of individuals and groups, or for the purposes of establishing boundaries between self and other (Kocka 1995a, p. 12; Koselleck et al., 1991). Of special interest, in this regard, is how such classificatory activity affects consciousness and social action. A central element in all definitions and research agendas is the question of exclusion and inclusion.

Exclusive Formations: Middle Class and Bourgeoisie

Exclusive formations of the middle classes include wealthy property owners, entrepreneurs, those with high salaries, the highly educated and highly qualified, as well as administrative, political, and cultural elites. These groups are characterized by similar economic and political situations. They are also linked through social networks and have similar cultural orientations and life-styles. Historical research has been directed toward eliciting the meaning of the concepts and categories just cited in concrete historical situations, and discovering the historically and regionally specific terms that allow them to be grouped together in a single formation. In England and the USA, this social phenomenon has, since the eighteenth and nineteenth centuries, been referred to as the 'upper middle class' or 'middle class' (singular). In francophone Europe, the relevant terms are *notables*, *bourgeoisie*, or *classe moyenne* (singular). The German-speaking peoples of Europe have employed the terms *Bürgerstand*, *Mittelstand*, or *Bürgertum*. The corresponding labels in Italy are *borghesia* or *ceti medi*, and in Spain *burguesía* (Kocka, 1995a; Zunz et al., 2001). In the nineteenth century, the bourgeoisie in this narrow sense made up approximately 5% of the population, although this percentage was somewhat higher in cities.

In contemporary scholarship, these formations are understood in terms of Max Weber's sociology of classes and status groups, and are referred to using the historical-systematic concept of the 'modern bourgeoisie' or 'middle class' (Kocka, 1995a; Zunz et al., 2001). Understood in this way, the bourgeoisie is a heterogeneous formation, which includes economically independent and dependent classes (both entrepreneurs and civil servants, both professionals and employees), the members of which have similar values and styles of life. The concept of the 'modern bourgeoisie' differs from the Marxian concept of the 'economic bourgeoisie.' The latter is defined in terms of the ownership of capital, access to the means of production, kinds of revenue, and strategies of capital deployment and commercialization. The economic bourgeoisie, which is the counterpart of the working class, is the central category of political-economic development theory. Historical scholarship that has been influenced by Karl Marx and Marxian theory distinguishes among the precapitalist bourgeoisie (speculative capital, merchant capital, usury) those land owners and agriculturalists who have a dynamic relationship to property and capital, the petite bourgeoisie of artisans, the bureaucratic bourgeoisie, the modern commercial and industrial bourgeoisie, and the monopolist bourgeoisie (Radandt et al., 1981). Since the late nineteenth century, the Marxian conception of the bourgeoisie has, in many variations, become established in scholarship and in public discussion. From the late nineteenth century and up until the 1980s, Marxian theory was also very influential in non-Marxian sociology and social theory as well.

More recently, the sociological and economic conceptions of the middle classes and the bourgeoisie have been challenged by cultural historians, who insist upon the central importance of phenomena which, in classical Marxian theory, are part of the superstructure. From a cultural historical perspective, membership in the middle classes depends primarily on particular ideas, values, attitudes, and sociocultural practices. Emphasis falls on the symbolic mediation of that which is bourgeois or middle class through discourses, images, institutions, and places of socialization and sociability such as the family, the school, the public sphere, the theater, literature, voluntary associations, coffee houses, festivals, architecture, and monuments. Research of this type leads to further important insights into the bourgeoisie. If, however, bourgeois culture is not linked back to the social groups that foster it, this kind of approach may become merely a socially diffuse cultural history of modernity.

Inclusive Middle Classes

The history of the exclusive middle class has been shaped by the need to establish distinct boundaries with reference to traditional elites, the working class, and the 'inclusive' or 'broad' middle classes. The 'inclusive middle classes' may seem to be less homogeneous than the exclusive bourgeoisie in terms of profession, status, education, income, style of life, attitudes, and values. Nevertheless, from the viewpoint of both historical actors and historians, they have often been thought to belong together. Their unity is often characterized with qualifying expressions such as 'finely graduated' or 'leveled.'

The factors that unite the inclusive middle classes vary from one land, historical period, and social situation to another. These common factors may include professional and economic interests, similar legal claims, traditions and mentalities, political viewpoints and voting behavior, similar hopes and fears with regard to upward or downward mobility, or attitudes with regard to style of life, which may in turn be oriented toward those of the exclusive bourgeoisie. The social spectrum of the inclusive middle classes extends from mid-level entrepreneurs to independent professionals, mid-level and low-level civil servants and employees, mid-level farmers and tenants, and even to workers with higher salaries and qualifications. When social, professional, and economic criteria are used to assess the size of this group in the Western and Central European countries of the nineteenth century, it may be estimated to have made up 15–30% of the total population. When other criteria are employed, this percentage may rise or sink.

In the USA and in France, the inclusive middle class is referred to as 'middle classes' or *classes moyennes* (plural), respectively. The corresponding term in Germany is *Mittelstand*, and in Switzerland *Mittelstand* or *Bürgertum* in the broadest sense of the term. In the German-speaking countries, the term *Volk* was also used in this sense, especially in the socially and politically most inclusive societies of the early twentieth century (Kocka, 1995a; Tanner, 1995; Savage, 2001; Charle, 2001). In the second half of the twentieth century, the concept of the inclusive middle classes has been extended even further.

As it gains in influence and in integrative potential, the older concept of the exclusive middle class seems to be falling increasingly into disuse.

It is common for both historical actors and historians to distinguish between historically older and newer groups of the broad middle classes. Master artisans and small businessmen are referred to as the *alter Mittelstand* (old middle estate) or the 'old middle class' (Haupt and Crossick, 1998). From the early nineteenth century and up to the 1970s, they have often been viewed as a historical relict and as potential victims of modernization. Employees i.e., members of the strata of white-collar workers, which has been expanding since the late nineteenth century and which continues to become increasingly differentiated, are referred to as the 'new middle class.' They are often thought to have developed a distinctive class consciousness at a relatively late date, due especially to their intermediate position between the bourgeoisie and the working class. In different societies and in different historical periods, employees may be understood either as agents or as victims of modernization (Mills, 1956; Kocka, 1977).

History of the Bourgeoisie and the Middle Classes

Recent scholarship on the eighteenth and nineteenth centuries has concentrated on the conditions and forms of the genesis of the modern exclusive bourgeoisie. The historiographical literature on the twentieth century focuses especially on the transformation, the crisis, and the declining significance ofthe exclusive bourgeoisie. With reference to the development of the modern bourgeoisie in Central and Northwestern Europe, Jürgen Kocka distinguishes between three phases, including an ascendant phase from the eighteenth to the early nineteenth century, a culminating phase from the middle of the nineteenth century to World War I, and a period of differentiation, dissolution, and even renaissance, which lasts into the late twentieth century (Kocka, 1995a,c). Attempts to assign the history of the broadly inclusive middle classes to historical periods usually posit a period of decline in the nineteenth century and a new period of ascendance in the twentieth century, which culminates in the inclusive middle-class society. In the following summary of the history of the bourgeoisie and the middle classes, reference is made to periods of 'genesis,' 'expansion,' and 'contraction.'

The Genesis of the Modern Bourgeoisie and Middle Classes (Eighteenth to Nineteenth Centuries)

The modern bourgeoisie took shape in the eighteenth and nineteenth centuries, though the precise time varied by region and by nation (Kocka, 1995b; Schrader, 1996; Gall, 1993; Charle, 2001). It included the following social groups: (1) the more dynamic part of the older urban bourgeoisie of the cities and communes; (2) those civil servants of the modern territorial state who were not part of the feudal hierarchy; (3) merchants, bankers, industrial entrepreneurs, and those members of the independent artisanry who were able to remove themselves from the order of the corporative estates; (4) professionals, literati, and artists; (5) enlightened or economically innovative portions of the landholding nobility, as well as non-noble estate owners and agriculturalists (in Southern and Western Europe the landowners often lived in cities, which is why they were counted among the bourgeoisie); (6) participants in emancipatory movements that were cultural or confessional, liberal or democratic, or regional or national in character.

Communication, symbolic representation, and social integration among the ranks of the bourgeoisie were promoted through institutional changes, which were implemented partly by the bourgeoisie itself, and partly by the monarchs and the state in the context of reforms and revolutions (freedom of trade, religious freedom, freedom of association, freedom of speech and of the press, political participation and accountability). The bourgeoisie developed its selfunderstanding and its language in the fields of the economy, culture, politics, and law. Bourgeois praxis developed in the representative organs of the estates, in free associations, in scientific academies, in literary circles and salons, in the print media, and in the reformed institutions of higher education, administration, law, legislation, and government. In these contexts, 'bourgeois' notions of collective and individual autonomy, representation, and the free play of public opinion were formed. In both the workplace and in public debates, new understandings of property and interest, ability and performance, self-cultivation and virtue, individual and society, contract and constitutions, and tradition and progress took shape. New experiences and discourses allowed the emerging middle class to criticize existing conditions, conceive of new social and symbolic orders, and lay claim to leading or mediating positions as well as to central functions and competences in society.

The bourgeoisie improved its chances for gaining favorable positions in a system of material, social, political, and cultural inequality by generalizing its own understandings of law and removing traditional privileges. It distanced itself from the traditional 'upper estates' of the court, the landed nobility, and the urban patriciate by adopting the role of a modern, dynamic, and achievement-oriented cultural and functional elite. It constituted itself in opposition to the nobility and the clergy as a 'third estate,' which represented the general public and was, in principle, open to everyone. The 'bourgeoisie' and the 'middle class' are concepts that imply a program and that serve to mobilize and justify certain forms of social action in the transition from estate society to class society. In principle, they ignore traditional differences of status, profession, and confession.

Typically, however, new forms of differentiation and new tensions arise fairly rapidly within the bourgeoisie, for example between the economic bourgeoisie (*Wirtschaftsbürgertum*) and the educated bourgeoisie (*Bildungsbürgertum*),between professional groups and status groups, between rural and urban groups, along local, regional, and national lines, among different confessions, or between political traditionalists and progressives or liberals and democrats. The integration of the bourgeoisie is a complicated and lengthy process, which usually succeeds only partially. The unity of the bourgeoisie is more a postulate than a reality (Banti, 1996; Siegrist, 1996). It is most evident in critical historical situations or in conflicts with others, to whom the bourgeoisie feels itself to be superior, whether morally, economically, politically, or in terms of

performance (nobility, manual laborers, the propertyless, the uneducated, the disenfranchised, and strangers or foreigners).

Contraction and Expansion: Bourgeosie and Middle Classes in the Nineteenth and Twentieth Centuries

In the process of the formation of the modern bourgeoisie, some groups of artisans and merchants, who previously belonged to the inclusive urban bourgeoisie, were economically marginalized and socially downgraded. In contrast, the educated bourgeoisie, merchants, and entrepreneurs belonging to ethnic and confessional minorities, and rural industrialists acquired new rights and gained in status. In England, the concept of the 'middle class' served to mobilize business people, industrialists, and mine owners from the provinces in the context of the electoral reform movement of 1832. It helped to integrate in a single group all of those who had not had the right to vote for the Lower House and who had felt themselves to be neglected by the upper middle class (London wholesalers and financiers, aristocratic landowners). Since the 1830s, in England as on the European continent, the interconnection among political, social, and legal rights possessed by the bourgeoisie had begun to emerge (Koselleck et al., 1991). This bundle of rights was viewed by bourgeois philosophers and social theorists as the very basis of political virtue in a well ordered society. In the course of the nineteenth century, in Europe and in the USA, perceptions of the 'bourgeois' or 'middle-class' male person became closely linked with the concept of the politically enfranchised 'citizen' (*citoyen*, *Staatsbürger*). In those parts of Central and Eastern Europe in which the political rights of citizens remained limited, property owners and the educated often shared political power at the local level. The towns and cities, in which various property-based or tax-based voting laws remained in effect until World War I, were, in many parts of Europe, the domain of the bourgeoisie. In Central Europe, the concept of the bourgeoisie lost much of its political content after the failure of the 'bourgeois revolutions' of 1848/49. Under these conditions, emphasis shifted to the cultural and aesthetic connotations of the concept. Throughout Europe, the bourgeoisie experienced significant gains in processes of 'inner' nation-building and cultural nationalization in the old nation-states, and through nationalist movements and the formation of new nation-states in Northern, Southern, and Eastern Europe.

Since the late nineteenth century, the bourgeoisie has continually renewed itself by incorporating members of new and expanded professional, functional, or status groups such as managers, engineers, planning and transportation experts, journalists, and high-level employees. These groups proliferated under conditions of intensified industrialization, commercialization, and urbanization or with the concentration of capital, the expansion of the role of science in society, increasing bureaucratization, and the rise of new communication media. The exclusive bourgeoisie allied itself increasingly, though not unreservedly, with social groups whose middle-class status was dubious, but who offered themselves as supporters of the established order. Tenants, agriculturalists with medium-sized holdings, and independent artisans and merchants were offered greater protection and drawn into the bourgeois alliance. Employees gained social and legal privileges over workers and were, thus, prevented from cooperating more closely with the socialist and trade-union organizations of the working class (Kocka, 1977).

At no time has the bourgeoisie been unchallenged. In the nineteenth century, the critique of the bourgeoisie was formulated from aristocratic, corporativist, Catholic, anti-Semitic, and socialist points of view. Since the late nineteenth century, the traditional, exclusive conception of the bourgeoisie has come increasingly under attack from members of social movements that arose within the bourgeoisie and the middle classes themselves. The leading concepts of the bourgeois progressives, social reformers, life-style reformers, and democrats are science, achievement, rationality, political equality, and social justice. Progressive and democratic critiques of the bourgeoisie contrast, however, with those of the authoritarian and conservative-elitist movements for renewal ofthe early twentieth century. The latter often attracted members of the bourgeoisie and petite bourgeoisie, even though they cultivated a specifically 'antibourgeois' discourse, in which the established and increasingly pragmatic bourgeoisie was accused of decadence and the inability to lead. In the twentieth century, antibourgeois sentiment formed a broad spectrum that ranged between conservative-corporativist and fascist programs, on the one hand, and communist ideology, on the other.

The concept of the exclusive bourgeoisie and antibourgeois discourses were supplemented in the twentieth century by conceptions of a broad and leveled-off middle class, which is typical of advanced industrial society. In the history of Europe and the USA, this perspective drew upon older ideas, such as those of social democratic, social-liberal, Christian-social, egalitarian, and communitarian traditions. After World War II, the USA made the concept of the inclusive middle class into a guiding principle for the reconstruction of the defeated states of Europe and Japan (Zunz et al., 2001). This concept unites socially, culturally, politically, and economically heterogeneous groups in a common vision of political and social citizenship in a democratic system and a market economy. During the era of the conflict between the East and the West, this vision was also motivated by a broadly based anticommunism i.e., by a rejection of a model of society, economy, and government that explicitly excludes the middle and claims to constitute society from below, under the leadership of the party of the working class.

In the noncommunist countries of Europe, in the first decades after 1945, those who wanted to conserve or renew the exclusive bourgeoisie of the past mounted an attack against the concept of the leveled and encompassing middle-class society. The exclusive bourgeoisie had lost prestige because of the Great Depression and due to the role that it had played in the fascist states. Now, however, its representatives mourned the waning and the demise of the bourgeoisie. Up until 1970 they warned of the decline of the bourgeoisie and the resulting threat posed to the nation and to Europe by 'mass culture,' 'consumer society,' 'Americanization,' 'materialism,' the 'welfare state,' the 'excesses' of democracy, the 'weakening of bourgeois values,' the 'loss of individuality,' and the 'leveled middle-class society' (Siegrist, 1994; Savage, 2001). The debate over the bourgeoisie experienced a new surge around 1968, which had, however, other causes, as the 'establishment,' on one hand, and students, intellectuals, socialists, and communists, on the others, battled

one another in the language of anti Marxism and Marxism. Since the 1970s, the discussion about the bourgeoisie has been superseded by debates over 'elites' and over traditional cultural, ethnic, and gender-based differences and discriminations within and outside the middle classes.

Middle Classes, Functional Equivalents, and the Limits of the Concept

The development of the middle classes in Eastern and Southeastern Europe, Latin America, Japan, and in the colonies and postcolonial societies of Africa and Asia differs considerably, both temporally and qualitatively, from that of core regions in the history of the middles classes. The concepts have their limits.

In many parts of the world in the nineteenth century, the bourgeoisie was hardly present. The social groups and the corresponding discourses, mentalities, and institutions were largely lacking. When concepts are imported and extended to phenomena that are more or less similar to the bourgeoisie, their meaning changes significantly (Kocka, 1995a,c). Marxian or economic and social historical studies, which, on the basis of theoretical premises and European concepts, identify bourgeois and middle-class groups in these areas, rarely do justice to their materials.

Recent approaches in the cross-national and cross-cultural comparative history of the middle classes focus on cultural and historical differences, and also on the specific meaning of similarities. Comparisons may show, for example, that institutional, economic, and technical innovations, which in Western and Central European history are associated with the bourgeoisie, are planned and carried out by other actors and groups in those areas without a bourgeoisie. In such cases, it is not very helpful to apply the concept of the bourgeoisie to such groups. Modernizing landowners in estate societies, civil servants in authoritarian states without a bourgeoisie, and rural and urban oligarchies and military leaders in preindustrial societies may be understood, at best, as 'functional equivalents' of the bourgeoisie. Latin American estate owners and the mercantile elite of large cities and ports may, in the course of the nineteenth century, have come to approximate the economic bourgeoisie. In societies that are sharply differentiated by status group and ethnicity, however, they form a political-social 'oligarchy,' rather than a 'modern bourgeoisie.' With the growth in the twentieth century of new agrarian, mercantile, bureaucratic, and industrial middle strata, the middle classes in such societies have expanded, and the traditional oligarchies have been forced to include them, at least to a degree, into the political elite (Florescano, 1985). Even then, however, the situation differs significantly from that in Europe.

In Eastern Europe in the nineteenth century, progressive groups of nobles, members of ethnic and confessional minorities, and Western-educated intellectuals and civil servants assimilated to the pattern of the bourgeoisie of Western and Central Europe. The formation of the bourgeoisie did not, however, proceed beyond the initial stages. In Southeastern Europe, modern middle classes began to emerge in the late nineteenth century, when, following the demise of the Ottoman empire, the segmented and not extremely hierarchical society changed into a national, centralized, and bureaucratic one. The national functional and cultural elites made the state into a resource and became a specific type of bourgeoisie (Höpken and Sundhaussen, 1998). In the communist societies of Eastern Europe, both genuinely and ostensibly bourgeois and middle-class groups were marginalized in the context of the communist program of the classless society under the leadership of the working class. Those who remained were, along with the new functionaries, redefined as members of the functional middle strata. The leading middle stratum was termed 'nomenclatura,' whereas the others were known as the 'service class' and the 'socialist intelligentsia.' Given this historical background, the problems involved in forming postsocialist middle classes are quite significant.

In twentieth-century Japan, where, previously, a historical bourgeoisie had hardly existed, there was a dramatic development of the inclusive middle classes. In the early twentieth century, the word *sarariiman* (salary-man), which at first meant scribe, office employee, and civil servant, became a catch-all term for members of the qualified, salaried middle classes (Gordon, 2001). Since the 1960s, the concept of *churyu* has become popular. This means 'mainstream' and includes all those who consider themselves to be modern, average, and normal with regard to attitudes toward work, family, consumption, and life-style. They make up the statistical and social 'middle mass' (Kelly, 2001), with which, in public opinion polls, 90% of the population aligns itself. The broad conception of the middle classes in Japan has its roots both in national ideas of community and in the inclusive view of the middle class that has been imported from the USA in the postwar period.

Historiography and Emphasis in Current Research

The exclusive bourgeoisie and (to a lesser degree) the broad middle classes have, from the very beginning, employed historical writing as a means of self-presentation, legitimation, community building, and self-reflection. History serves the bourgeoisie as a means of locating itself in space and time, and orienting itself in a modern, dynamic society, which it seeks constantly to transform and to stabilize. The historiography of the middle classes is characterized, first, by teleological notions of progress and modernization; second, by a narrative of crisis and decadence and of danger and dissolution, which draws upon older religious and aristocratic motifs but is subsequently transformed and takes on a life of its own; and, third, through the motifs of conservation and stabilization. Central elements of this history are elevated by the bourgeoisie and middle classes to the status of norms and, thereby, dehistoricized. They then take on the form of myths or theories of law, society, and development, which are insensitive to variations in era and context. The bourgeoisie displays a tendency toward idealizing, sacralizing, and naturalizing its own past. For this reason, its historiography has often been the target of historians of various ideological or social provenance, who are critical of or opposed to the bourgeoisie.

Until the 1970s, the history of the bourgeoisie and the middle classes was, by and large, written from the perspective

of either proponents or opponents. Since the 1980s, historical research on the bourgeoisie has, in some important senses, become more impartial, more independent, more scientific, and more innovative. Traditional versions of history at local and national levels have been relativized and revised with reference to interdisciplinary, international, and comparative approaches in historical research (Kocka 1995b; Siegrist, 1996). As a result of a stronger focus on the dimensions of 'gender' and 'religion' (Hall and Davidoff, 1987) as well as 'ethnicity,' new perspectives have been achieved with regard to the periodization and evaluation of historical materials. In Europe and, to a somewhat lesser degree, the USA, the bourgeoisie and the middle classes rank among the best researched topics in historical scholarship.

Bowlby, John (1907–90)

Joan Stevenson-Hinde, University of Cambridge, Cambridge, UK

Abstract

The son of Sir Anthony and Lady Bowlby, John was the fourth born of six children. During daily life, both parents were rather distant, with child care given over to nursemaids and then boarding school at 11. Bowlby's later clinical observations and research indicated that separations could have lasting effects. He found an explanation not in the analytical thinking of the time, but in ethology. This enabled a view of attachments as an integral part of human nature, with attachment behavior selected for during the course of evolution along with its complement, caregiving behavior. When effective, attachment behavior leads to a feeling of security, and when ineffective to acute or chronic anxiety, as indeed happens with separations. The development of attachment theory and its implications are outlined.

Edward John Mostyn Bowlby was born in London on 26 February 1907 to Mary Bridget Mostyn and Anthony Alfred Bowlby. They had six children, who were usually referred to in groups of two: 'the girls' (Winnie and Marion), 'the boys' (Tony and John), and 'the babies' (Jim and Evelyn). Only 13 months apart, 'the boys' had a close relationship, including intense rivalry. But in addition to keeping his end up with a slightly older brother, John was caring toward a younger brother with chronic problems due to a thyroid deficiency, discovered too late to be cured. John was born at a time when it was customary for an upper-class mother to hand over her children to a nanny and nursemaids. The nanny in charge practiced a firm, regular, and disciplined routine. A particular nursemaid took care of John on a daily basis. He loved her, and years later she said that she was always fondest of John. However, she left the family when John was about four. The effect of this on John is unknown, as he never discussed it (van Dijken, 1998). The Bowlby children saw their mother for a short time each day, and their father on Sundays. Their father, who was knighted in 1911 as a result of being a surgeon to royalty, was absent even more during World War I. However, there were long family holidays in the country to the New Forest in July and to Scotland in late summer. This remained a family tradition with John, his wife Ursula, their four children, and later their grandchildren retreating to the Isle of Skye each summer. John did much of his writing there, as well as walking and enjoying the 'season,' including the Skye Ball with its Scottish reels. Skye is where John died on 2 September 1990. John, and later Ursula, are buried there in a remote churchyard above the cliffs and the sea.

When John was 11, he and Tony were sent off to boarding school. From there, John went to the Royal Naval College, Dartmouth. But at 17, he decided that the Navy was not for him, writing to his mother that he wanted a job, which would "improve the community as a whole" (van Dijken, 1998: p. 46). At Trinity College, Cambridge, John followed his father by studying medicine, with a departure into psychology in his final year, graduating in 1928. Rather than going straight into clinical school, John spent a year teaching in two boarding schools, including one for disturbed children. Their histories of disrupted childhoods impressed Bowlby, and he decided to combine his medical training at University College Hospital with psychoanalytic training at the Institute of Psycho-Analysis. After becoming medically qualified in 1933, Bowlby went to the Maudsley to train in adult psychiatry, and then to the London Child Guidance Clinic in 1936. He became an Army psychiatrist in 1940, and after the war he went to the Tavistock Clinic, where he remained.

Having begun analysis with Joan Riviere, Bowlby went on to qualify as an analyst in 1937 and then to train in child analysis with Melanie Klein. Differences grew concerning the importance of real-life experiences over unconscious fantasies. For example, when treating a hyperactive and anxious 3-year-old boy, Bowlby noted that the boy's mother was having a breakdown and had been admitted to mental hospital. Klein, however, did not allow Bowlby to treat the mother, devaluing what was actually happening in the child's life. Yet Bowlby was keenly interested in what happened, thanks to his love of nature, his scientific training, and his clinical observations (Holmes, 1993).

The Theme of Separation

Bowlby was particularly interested in what happened around separation. This interest may have sprung from his own childhood experience, as well as his work with maladjusted children in boarding school and later in the clinic. "I was struck by the high incidence of severely disrupted relationships with mother-figures in the early histories of children and adolescents who had been referred to the clinic on account of repeated and apparently incorrigible stealing." Bowlby's research for the WHO gave him the opportunity to survey the field and make personal contact with leading psychiatrists and psychologists in the United States and the continent, culminating in his influential WHO report (1952). His study with Joyce and James Robertson on children going to hospital indicated, in Bowlby's own words, that "First-hand observations of young children admitted to residential nursery or hospital and not visited by parents revealed the intense and prolonged distress they suffer. Moreover, visits home showed that the child's relationship with the mother is seriously disturbed for weeks or longer after

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61014-0

reunion. These observations lent considerable support to the hypothesis that the experience of separation and loss of mother-figure in the early years could have adverse effects on development, at least in some cases. That raised a question: if the disruption of a child's relationship with mother-figure in the early years creates much distress and anxiety, what is so special about the relationship that has been disrupted?" (1991a: pp. 302–303). The prevailing answer was that bond formation stemmed from the association of mother with the provision of food, thereby satisfying a primary need. But in Bowlby's view, this "cupboard love theory" (p. 303) was insufficient. Both experimental observations and a theoretical framework were lacking (for a full account of the transition from psychoanalysis to ethology, see van der Horst, 2011).

An Ethological Perspective

In the summer of 1951, Bowlby came across Lorenz's concept of imprinting and was encouraged by Julian Huxley to pursue ethology further. He recommended two new books, Lorenz's *King Solomon's Ring* and Tinbergen's *The Study of Instinct*. Bowlby spent some months 'mugging up on ethology' as well as making personal contact with the authors. In early 1954, Bowlby met Hinde at a meeting on ethology and psychiatry in London, where they were invited to speak in place of Lorenz and Tinbergen, who could not come. This led to Bowlby inviting Hinde to join his weekly seminar, held in a dingy room in the old Tavistock in Beaumont Street. The group was entirely heterogeneous: a Freudian and a Kleinian analyst, a Hullian and a Skinnerian learning theorist, a Piagetian, an ethologist, sometimes an antipsychiatrist, psychiatric social workers, having in common only an interest in parent–child relations. Bowlby's intellectual dynamism and judicious enthusiasm held the group together. During that period, Bowlby formulated his ideas on 'a child's tie to his mother' and 'separation anxiety.'

From an ethological perspective, the occurrence of species-characteristic behavior suggests that such behavior may have been selected for during the course of evolution. Bowlby applied this thinking to attachment behavior defined as any form of behavior, which attains or maintains proximity to a caregiver in times of need or stress. He argued that individuals who exhibited attachment behavior would have been more apt to survive and leave offspring who in turn would reproduce, compared with those who did not. Obviously selection for attachment behavior could not have happened without a similar pressure on its complement, caregiving behavior. "During the course of time, the biologically given strategy of attachment in the young has evolved in parallel with the complementary parental strategy of responsive caregiving, the one presumes the other" (Bowlby, 1991b: p. 293).

Bowlby further suggested that attachment behavior reflects a distinct motivational system in its own right, not dependent on prior association with any other motivational system such as hunger. Bowlby postulated that the biological function of attachment behavior is protection from harm, by keeping a child in touch with one or more caregivers. With this approach, activation of a fear behavior system would lead to activation of the attachment behavior system. Attachment behavior would lead to proximity to the caregiver, which would in turn deactivate the fear system, enabling activation of an exploratory or social system (e.g., Bowlby, 1969/1982).

Bowlby realized that an evolutionary argument could provide insight into behavior, which otherwise appeared abnormal. "It is against this picture of man's environment of evolutionary adaptedness that the environmentally stable behavioural equipment of man is considered. … not a single feature of a species' morphology, physiology, or behavior can be understood or even discussed intelligently except in relation to that species' environment of evolutionary adaptedness" (Bowlby, 1969/1982: p. 64). Bowlby used this reasoning to understand as 'natural' the occurrence of 'irrational fears' as well as the occurrence of attachment behavior throughout the life span. In considering the fears of childhood, such as fear of strangeness, separation, or darkness, Bowlby disagreed with influential analysts such as Klein or Freud who had labeled them as irrational. Instead he argued that our tendency to fear what had been dangers in the environments in which we evolved is "to be regarded as a natural disposition of man … that stays with him in some degree from infancy to old age … Thus it is not the presence of this tendency in childhood or later life that is pathological, pathology is indicated either when the tendency is apparently absent or when fear is aroused with unusual readiness and intensity" (Bowlby, 1973: p. 84).

Similarly, attachment behavior in times of stress should not be viewed as a sign of weakness, even beyond childhood. Long before research began on the role of attachment in adulthood, Bowlby wrote "such tendencies … are present not only during childhood but throughout the whole span of life. Approached in this way, fear of being separated unwillingly from an attachment figure at any phase of the life-cycle ceases to be a puzzle, and instead, becomes classifiable as an instinctive response to one of the naturally occurring clues to an increased risk of danger" (Bowlby, 1973: p. 86).

In one of his final contributions, Bowlby summed up thus, "Once we postulate the presence within the organism of an attachment behavioural system regarded as the product of evolution and having protection as its biological function, many of the puzzles that have perplexed students of human relationships are found to be soluble. … an urge to keep proximity or accessibility to someone seen as stronger or wiser, and who if responsive is deeply loved, comes to be recognised as an integral part of human nature and as having a vital role to play in life. Not only does its effective operation bring with it a strong feeling of security and contentment, but its temporary or long-term frustration causes acute or chronic anxiety and discontent. When seen in this light, the urge to keep proximity is to be respected, valued, and nurtured as making for potential strength, instead of being looked down upon, as so often hitherto, as a sign of inherent weakness" (Bowlby, 1991b: p. 293).

Development of an Attachment Bond

Thus, an attachment behavior system, organized as a distinct motivational system, gives rise to attachment behavior when activated by stress, particularly threats or perceived threats of separation. An infant is born with "a marked bias to respond in special ways to several kinds of stimuli that commonly

emanate from a human being" (Bowlby, 1969/1982: p. 265). As attachment behavior develops, it forms the basis for an inferred attachment bond. Bowlby described particular phases in its development: preattachment (from birth to about 2 months), involving signaling without discriminating one person from another; attachment-in-the-making (2–6 months) where signals become directed to particular persons; clear-cut attachment (0.5–4 years) with locomotion and goal-corrected behavior; and finally a goal-corrected partnership (4 years onward) with perspective taking, communication skills, and sharing mutual plans. Although additional attachments may develop throughout life, these early attachments endure. What is not common to all individuals is the quality of attachment, which tends to be consistent throughout life, and is reflected in the three basic patterns: avoidant, secure, and ambivalent. Although Bowlby has been mistakenly quoted as stating that such patterns are indelibly 'fixed' over the first year, he in fact stressed that any continuity must depend on a continuous flow of interactions. "It is evident that the particular pattern taken by any one child's attachment behavior turns partly on the initial biases that infant and mother each bring to their partnership and partly on the way that each affects the other during the course of it" (Bowlby, 1969/1982: p. 340). Bowlby continues, "By the time the first birthday is reached both mother and infant have commonly made so many adjustments in response to one another that the resulting pattern of interaction has already become highly characteristic" (Bowlby, 1969/1982: p. 348). In addition to the immediate characteristics of the infant, the behavior of the caregiver is determined by "the particular sequence of environments, from infancy onwards, within which development takes place" (Bowlby, 1969/1982: p. 378). Thus, while a consistent cycle of interactions tends to maintain a given quality of attachment, if the cycle were to change, then so would the pattern of attachment.

As to which pattern of attachment is desirable, Bowlby was concerned with what might be called 'psychological desiderata.' However, other perspectives may prevail, such as 'biological desiderata' for increasing inclusive fitness, or 'cultural desiderata.' Although influencing each other, the three desiderata, biological, psychological, and cultural, may differ, especially in modern industrialized societies (Hinde and Stevenson-Hinde, 1991). Nevertheless, it was 'psychological well-being,' which Bowlby as a practicing psychiatrist regarded as basic. Making an analogy with 'physical well-being,' Bowlby argued that 'psychological well-being' had an absolute meaning, with security of attachment an essential ingredient. Security in turn depends on antecedent interactions with a 'sensitively responsive' mother, as found in Mary Ainsworth's pioneering Baltimore study (Ainsworth et al., 1978) and subsequently in many others. In a review chapter, van IJzendoorn and Bakermans-Kranenburg (2004) conclude that correlational, experimental, and cross-cultural studies have replicated the association between sensitivity and attachment numerous times. Thus the main tenets of attachment theory appear to be universal: (1) the phenomenon of infants showing attachment behavior from birth, leading to (2) the formation of an attachment bond with one or more specific caregivers; and (3) the security of that attachment bond dependent upon antecedent caregiver responsiveness to infant's signals.

Assessing the Quality of Attachment

Bowlby's collaboration with Mary Ainsworth (1913–99) remains a model for creativity in science. Their friendship spanned 40 years, from 1950 when Ainsworth joined Bowlby at the Tavistock. After her longitudinal study of mother–infant behavior in Uganda, Ainsworth joined the faculty at the Johns Hopkins University in 1955. Appreciating that assessments of attachment must involve how a child uses mother as a 'secure base' when the attachment behavior system is activated, Ainsworth developed a Strange Situation procedure for infants (12–18 months old; Ainsworth et al., 1978). This was modified for older children, with her guidance (2.5–4.5 years: the Cassidy and Marvin system; 6 years: the Main and Cassidy system; reviewed by Solomon and George, in Cassidy and Shaver, 1999/2008). Ainsworth's procedure paved the way for empirical studies to explore the framework provided by Bowlby.

The Strange Situation procedure involves a series of episodes in an unfamiliar laboratory setting, including two separations and two reunions from an attachment figure. The coding emphasis is on the reunion episodes, which show how the child organizes behavior to mother following the stress of separation. A secure pattern involves the child-greeting mother with full gaze and positive affect. Interactions are calm, while also intimate and indicative of a special relationship. The two main insecure patterns may be contrasted with this, and indeed with each other. Whereas the avoidantly attached child shows minimal responses and maintains neutrality, the ambivalently attached child emphasizes dependence on mother, with angry/whiny resistance and/or immature behavior. A disorganized pattern reflects confusion and apprehension. Beyond infancy, one may see a transition from disorganization to a controlling pattern, reflecting an effort to reduce uncertainty by taking charge.

The move beyond behavioral observations to the level of representation was largely inspired by one of Mary Ainsworth's former PhD students, Mary Main. Once children reach Bowlby's 'goal-corrected partnership' stage, their verbal behavior may be used to index representations of attachment (reviewed by Solomon and George, in Cassidy and Shaver, 1999/2008). Mary Main and colleagues developed the Adult Attachment Interview (AAI), based around 18 questions designed to access one's current state of mind with respect to attachment. Correspondence between parents' AAI classifications and their infants' Strange Situation classifications has now been reported in many studies (reviewed by Hesse, in Cassidy and Shaver, 1999/2008).

Emotional Communication

In Bowlby's own words, "Thus what is happening during these early years is that the pattern of communication that a child adopts towards his mother comes to match the pattern of communication that she has been adopting towards him. Furthermore, from the findings stemming from the Adult Attachment Interview, it seems clear that the pattern of communication a mother adopts towards her infant and young child is modeled on the pattern characteristic of her own intrapsychic communications. Open and coherent intrapsychic communication in a mother is associated with open and

coherent two-way communication with her child, and vice versa" (1991b: pp. 295–296). To Bowlby, "the concern of a psychoanalyst is not only with the extent to which a patient feels free to express his emotions openly, but with the prior questions of whether he knows what his feelings are and what has aroused them" (1991b: p. 294).

One reason for the success of attachment theory is that it lies at the heart of our emotional life. "Many of the most intense emotions arise during the formation, the maintenance, the disruption and the renewal of attachment relationships. The formation of a bond is described as falling in love, maintaining a bond as loving someone, and losing a partner as grieving over someone. Similarly, threat of loss arouses anxiety and actual loss gives rise to sorrow; while each of these situations is likely to arouse anger. The unchallenged maintenance of a bond is experienced as a source of security and the renewal of a bond as a source of joy" (1991a: p. 306).

Implications

Normative Development and Parenting

The implications of attachment theory for the development and expression of emotions within close relationships, including how patterns may be transmitted across generations, are clear from the above. Furthermore, the sense of security, which must underlie any appreciation of emotions within one's self and their expression to others depends upon having attachment figures who are sensitively responsive to emotional needs. Bowlby postulated that experiences within early close relationships lead to an 'internal working model' of the self in relation to others that guides future interactions. With a secure working model comes the expectation of gaining support when it is needed, along with feeling worthy of such support. Empirical studies have related security to particular developmental outcomes, including resilience, empathy, and social competence (reviewed in Weinfield et al., in Cassidy and Shaver, 1999/2008). A classic study – the Minnesota Longitudinal Study of Risk and Adaptation from Birth to Adulthood – involved a variety of assessments in multiple contexts of 180 children born into poverty. Security in infancy was a predictor of adaptation in playgroup, which along with security was an additional predictor of social competence in middle childhood. The Minnesota study illustrates how early close relationships may set the stage for later ones, which along with changing circumstances may affect the outcome, in a probabilistic way. With its range of assessments and outcomes over time, the Minnesota study supports the view that attachment status should not and does not predict every aspect of development.

Finally, cross-cultural studies highlight the need to take a child's network of early relationships into account in predicting the outcome (van IJzendoorn & Sagi-Schwartz, in Cassidy and Shaver, 1999/2008). A further challenge involves defining and assessing attachment-related outcomes in culturally appropriate ways (Chen and Rubin, 2011).

Psychopathology

Attachment theory has direct implications for disorders related to separation or loss, such as abnormal grief, neurotic depression, or agoraphobia (see Holmes, 1993). Furthermore, particular patterns of insecure attachment may shed light on aspects of parenting that might be modified to promote security. For example, the disorganized pattern, often seen in clinical samples, appears to be associated with fearfulness in either parent or child or both, thereby suggesting a window for intervention (Lyons-Ruth & Jacobvitz, in Cassidy and Shaver, 1999/2008). Concerning the early onset of disruptive behavior problems, Deklyen & Greenberg (in Cassidy and Shaver, 1999/2008) propose a 4-factor risk model, which includes attachment. In their own words, "attachment theory provides a critical developmental frame for understanding *how* caregiving relationships influence processes thought to be central to emerging psychopathology – for example, the construction of cognitive-affective expectancies, the capacity for emotional and behavioral regulation, and strategies for coping with stress" (p. 637).

Social Policy Issues

When a child goes to hospital, we now take it for granted that parents may visit or even live in. However, before Bowlby's influence, hospital practice involved leaving caregiving to the experts and keeping attachment figures away. Obstetric practice followed similar lines. Bowlby (1953) did not hesitate to challenge this: "reflect for a moment on the astonishing practice which has been followed in obstetric wards of separating mothers and babies immediately after birth and ask … whether this is the way to promote a close mother–child relationship. It is hoped that this madness of western society will never be copied by so-called less developed societies." Such concern over separation from attachment figures remains relevant to current provision of care, whether for children placed in multiple foster homes with long delays until adoption or for adults, such as the elderly and mentally ill.

Regarding day care, Bowlby was keen to put right the misinterpretation of what he wrote. In stressing the importance of early caregiving, he did not mean that a parent must be with the child all the time. From the above it will be clear that attachment theory is about the quality of a relationship rather than amount of time spent together. Similarly with adoption, attachment theory does not say that early adverse experience cannot be overcome. Indeed the implication is that adoptive parents, if sensitively responsive to the child's needs, may do a great deal to set interactions in a cycle that will promote security.

Finally, attachment theory has been applied to the level of society. As a professor of social planning has urged, "We need also to institute a style of governing our relationships with each other which takes as its first principles reciprocity of commitment, predictability, and respect for the unique structure of meaning and attachment which makes life worthwhile for each of us." Such an argument implies the "need to create a world in which we dare become attached" (Marris, 1991: p. 89).

Conclusion

Bowlby's framework for understanding a core aspect of development is set out in his trilogy, *Attachment and Loss*

(1969/1982, 1973, 1980). The fruits of his theory are gathered together in the first and second editions of the *Handbook of Attachment* (Cassidy and Shaver, 1999/2008) dedicated to John Bowlby and Mary Ainsworth. Each edition is organized into six sections, with the present (2008) edition consisting of: Overview, Biological perspectives, Attachment in infancy and childhood, Attachment in adolescence and adulthood, Psychopathology and clinical applications, and Systems, culture, and context.

The last major publication of Bowlby himself was a biography of Charles Darwin (Bowlby, 1991c). With a convincing application of attachment thinking, Bowlby explained Darwin's lifelong psychosomatic symptoms in terms of unmourned loss of mother at the age of 8. Additionally, a keen reader may find parallels between the two men. Like Darwin, Bowlby had a distant father who was a doctor, both were younger sons, both were open to evidence, and both lacked rancor toward their detractors. Finally, it might be said of their theories that they have the quality of immediacy and 'obviousness.' In retrospect it seems obvious that species have evolved by natural selection, that people are attached to one another and suffer when they separate "but it took child-like simplicity of vision combined with mature determination and attention to detail to root out the obvious and to create for it a secure theoretical base" (Holmes, 1993: pp. 34–35; see also van Dijken, 1998).

This article is a revision of the previous edition article by W.J. Hoyer, volume 2, pp. 1318–1321, © 2001, Elsevier Ltd.

Abstract

Normal or typical age-related changes in brain mechanisms have consequences for cognitive and personality function during the adult years and in old age. In recent years, much has been learned about cellular and molecular details of brain aging from advances in basic sciences. Advances in the understanding of the neurobiological bases of complex human behavior have come about through improved brain-imaging technologies and improved quantitative modeling of the dynamic relations between brain aging and behavior. New findings and theoretical models that attempt to link advances in the understanding of brain aging with observations of age-related changes in behavior, cognition, and personality point to the dynamic interplay between behavior and brain. Concepts of brain plasticity, cognitive plasticity, cognitive reserve, and compensation are emphasized in much of the recent research on the relations between brain aging and its consequences for cognitive and personality. Progress in this area informs the understanding of the potentials and limits of human aging and conceptualizations of interventions for healthy aging.

Introduction

Throughout the life span, a complex interplay of developmentally dynamic neurobiological mechanisms, genetic factors, environmental factors, and the individual's actions and experiences yields a range of manifestations that are expressed in the cognitive and personal attributes of individuals (e.g., see Lövdén et al., 2010). Generally, healthy older adults show age-related cognitive deficits in situations that require the management and coordination of multiple tasks or that involve delayed recollection of details about events or experiences (for a review, see Verhaeghen, 2013). Age-related cognitive deficits are most prominent in tasks that depend on hippocampal and prefrontal brain circuitry. In terms of personality, healthy individuals usually show only minor changes in personality traits across the adult years. Although the consequences of brain aging on personality across the adult life span are usually not readily observable, recent evidence suggests that particular personality traits influence brain aging mechanisms and age-related differences in neuroanatomical integrity (e.g., Hill et al., 2011). Further, it is well-known that some personality traits are associated with greater mortality risk, whereas other personality traits are associated with greater longevity and increased adherence to health-promoting activities (e.g., medical adherence, dietary behavior, exercise). Cognitive and social behavior and personality attributes have consequences for healthy aging, morbidity, and mortality risk.

Scientific knowledge about the specific relations between brain aging, cognition, and personality has increased tremendously in recent years, due to advances in brain science, epigenetics, and in application and resolution of noninvasive techniques for assessing brain–cognition–personality relations, such as structural and functional magnetic resonance imaging (fMRI) and positron emission tomography (PET). Recent advances in neuroimaging allow identification of the brain regions associated with age-related changes in selected cognitive functions. One relatively new technique, magnetic resonance diffusion tensor imaging (DTI), is useful for characterizing the integrity of anatomical connections and white-matter circuitry and provides a quantitative assessment of white-matter microstructure. For example, DTI studies show that the greatest amount of age-related alterations in white matter occur in the prefrontal cortex and the anterior corpus callosum. The kinds of cognitive tasks that show the largest age-related deficits depend on exactly these brain regions.

This article emphasizes the idea that the aging of brain–cognition–personality relations is a consequence of the interplay between multiple etiologies and moderators that involve not only neural mechanisms and structural changes in the brain, but also the influences of genetic factors, environmental factors, and health and lifestyle experiences of the individual. We begin this article with a brief summary of brain aging and plasticity of function, and cognitive reserve. Then, we discuss recent advances in the understanding of the relations between brain aging, cognition, and personality.

Brain Aging

Brain aging reflects time-based alterations in a variety of neuroanatomical and biochemical structures and functions. Structurally, MRI data using voxel-based morphometry show age-related shrinkage in the volume of the ventricles of the brain, and show that the degree of shrinkage varies somewhat for different brain regions. The ventricles are interconnected cavities within the brain that contain cerebrospinal fluid. Because the ventricular cavities are interconnected, changes in the ventricular system can be considered to be a fair index of the general health of the brain. As the brain shrinks in size with aging, the ventricles expand to take up more space.

Neurogenesis refers to the production of new neurons originating from stem cells and progenitor cells. Stem cells are unprogrammed cells that divide and can change into cells with specialized functions. A host of factors (including individually controlled actions such as exercising and maintaining a healthy diet) can stimulate or deter neurogenesis. The hippocampus, a brain region that is centrally involved in associative learning and memory, is known to produce new neurons throughout life (e.g., Deng et al., 2010). A steady production of new neurons supports effective hippocampal function, whereas

deterred neurogenesis eventually results in memory failure. Cognitive health is associated with increased neurogenesis and the strengthening of particular pathways in the hippocampus in line with functional demands (e.g., Hertzog et al., 2009).

Neural integrity and neural functions are impaired by the accumulation of beta amyloid and by inflammations within the environment of neurons. Within-brain environmental factors affect the vitality of neurons and their physiology. Epigenesis refers to the premise that development throughout life roughly follows a genetic plan, and that the plan is modifiable by the turning-on and turning-off of genes in response to experiences and environmental factors. For example, either acute or chronic exposure to toxins can accelerate inflammation in the central nervous system. Thus, the course and rate of genetically programmed aging depend on a host of within-brain factors and external factors.

Aging of Brain–Cognition–Personality Relations

Intraindividual changes in cognition depend on the interplay between neural mechanisms and brain structures, genetic influences, and environmental influences. For example, the Catechol-*O*-Methyltransferase (COMT) genotype affects age-related variability in decision time in younger and older adults (Li et al., 2010). The COMT gene affects the degradation of dopamine in the prefrontal cortex. Dopamine is manufactured in the cells of the substantia nigra and travels in the pathways connected to the frontal cortex. Dopaminergic systems normally decline with aging across various brain regions. Age-related reductions in dopamine are known to have detrimental consequences for cognitive and psychomotor functions including the planning and execution of actions (Bäckman et al., 2010). Compared to older individuals with a genetic predisposition for efficient dopamine signaling in the prefrontal cortex, older individuals with a genetic predisposition for less-efficient dopamine signaling in the prefrontal cortex show greater variability in performance and an overall lower rate of information processing when carrying out a simple two-choice perceptual decision task (Li et al., 2010).

A relation between the Cholesterol Ester Transfer Protein (CEPT) genotype and cognitive function has also been demonstrated (Barzilai et al., 2006). A variant of the CEPT genotype is associated with preserved cognitive function in very old adults. This variant is associated with lower CEPT levels and a favorable lipoprotein profile. These and other findings of associations between particular genetic variants and polymorphisms, and differences in relative efficiency of neuromodulation and cognitive function point to the necessity of a multicausal view in building a comprehensive understanding of developmental changes in brain–cognition relations.

Recent research suggests that a fundamental issue in the understanding of brain aging has to do with change in the effectiveness of switching between two brain networks, the default network and the attention network (e.g., Spreng and Schacter, 2012). The default network is an integrated system of regions that includes the medial prefrontal cortex, posterior cingulate cortex, superior frontal gyrus, medial and lateral temporal lobes, and the posterior part of the inferior temporal lobe. The default network is active in internally focused tasks such as autobiographical memory, imagining the future, and social cognition. In contrast, the attention network is an integrated system of regions that includes the dorsolateral prefrontal cortex, frontal eye fields, inferior precentral sulcus, middle temporal motion complex, and superior parietal lobe. The attention network is active in externally driven tasks, such as processing and making responses to visual-spatial information. A third neural network, referred to as the control network, expedites the shift between the default network and the attention network in response to changing internal and external states. The regions of the control network include rostrolateral prefrontal cortex, middle frontal gyrus, precuneus, the anterior extent of the inferior parietal lobe, dorsal anterior cingulate, and the anterior insula. Thus, the control network is anatomically interposed between the default network and the attention network, and serves to facilitate the ability to rapidly adapt thoughts and behaviors to changing internal states and external stimuli. In a recent study examining the interactivity of these networks during autobiographical memory and visual-spatial planning tasks in young adults and older adults, it was found that young adults could efficiently deactivate the default network and that older adults failed to do so. The failure was not due to default network dysfunction, but rather to a failure to a lower degree of flexible network interactivity.

Brain and Cognitive Plasticity

Maintenance as well as change in effective cognitive function depends on the adaptability of brain functions (within constraints) in response to experience. Normal neurobiological aging brings with it across-the-board compromise in a wide range of cognitive functions. However, cognitive performance can be enhanced or at least maintained by experience via whatever allowances and compensations there might be in the neural circuitry of individuals as they grow older. Concepts of experience-based plasticity are now prominent in neuroscience.

Neuronal viability is significantly involved in normal brain aging. Shrinkage of dendritic branching and other changes in neuronal viability and in the neural architecture with aging are central to the understanding of age-related changes in cognitive function. Various aspects of biological aging conspire to produce age-related losses in behavioral and cognitive function. Current theories of biological aging emphasize genetically programmed deficits, the cumulative negative consequences of mutation, and the cumulative negative effects of wear and tear on function. Among the brain areas most affected by aging are the frontal-striatal circuits of the caudate. Other areas that are known to be substantially affected by normal brain aging are the prefrontal cortex and the dense network of projections connecting the prefrontal cortex and subcortical monoaminergic nuclei. The extent of age-related deterioration is also substantial for the posterior association areas and the neostriatum. The primary sensory areas of the brain are largely unaffected by aging. In light of findings of preserved brain function in the sensory areas, reliable declines in sensory efficiency with aging are attributed to receptor function and peripheral neural function (e.g., see Bennett et al., 2009).

The main, general source of behavioral deficits associated with aging is known to be general slowing in the speed of mental processes. Age-related slowing in the speed of encoding, perceiving, processing, retrieving information accounts for a substantial part of the variance in comparisons between the performance of younger and older adults across a wide range of tasks (e.g., for a comprehensive meta-analytic review, see Verhaeghen, 2013). Specifically, in 1354 young-old data pairs, Verhaeghen (2013) found that the performance of older adults could be quantitatively described in terms of a ratio of between 1.2 and 1.7 of the performance of young adults. Variation in the size of ratio was associated with type of task; the slowing factor for tasks associated with the temporal lobes was about 1.2; the slowing factor for tasks associated with the frontal lobes was about 1.3; the slowing factor for tasks associated with the occipital lobes was about 1.5; and the slowing factor for tasks associated with the parietal lobes was 1.8.

Age-related slowing in cognitive performance across tasks may be associated with a number of brain aging phenomena such as changes in neurotransmitter substances at the synapse, neural demyelination, disruptions in neural circuitry-related vascular lesions, and increases in the extent or amount of recruitment and activation of brain volume. With regard to possible age differences in the amount of recruitment of brain areas, the results of several recent fMRI studies suggest that more cognitive resources are required for older adults than for younger adults to carry out cognitive tasks (e.g., see Reuter-Lorenz and Park, 2010). In these studies, younger persons showed a relatively well-defined pattern of activation involving the inferior prefrontal-orbitofrontal cortex during the encoding of episodic information, and involving the right prefrontal cortex during the retrieval of episodic information. In contrast, older adults showed more widespread activation patterns at encoding and retrieval.

Much of the work in the cognitive neuroscience of aging has focused on age-related memory loss. Some aspects of memory function show large deficits associated with normal aging, whereas other aspects of remembering appear to be relatively unimpaired in healthy older adults (e.g., semantic priming, implicit memory). Relatively substantial age-related declines in cognitive function can be observed in tasks that entail the active and simultaneous processing and storing of information. This kind of processing, referred to as working memory, is a key component of cognitive tasks that require juggling lots of information at once. Research bearing on the neural substrates underlying age-related deficits in working memory suggests that working memory requires cooperation among scattered areas of the brain. Which specific areas are activated depends on whether the task requires spatial or semantic memory. Working memory has been associated with the prefrontal cortex. Structural imaging studies indicate shrinkage of the prefrontal cortex with aging. However, functional imaging studies indicate increased activation in the prefrontal areas for older adults than for younger adults. These findings can be interpreted as suggesting that older adults use more cognitive resources to carry out demanding cognitive tasks.

It has been proposed that there are two kinds of reserve that protect and support function in the face of brain pathology; brain reserve and cognitive reserve. Brain reserve refers to measures of brain vitality, brain size. Cognitive reserve is based on observations that individuals differ in their ability to sustain effective cognitive function in the presence of brain pathology. Evidence supporting the cognitive reserve hypothesis demonstrates that individuals with higher cognitive reserve show better maintenance of effective cognitive function than individuals with lower cognitive reserve (Ewers et al., 2013).

Although brain aging phenomena do not have obvious consequences for personality changing during the adult years, there is clear evidence showing that selected personality attributes have consequences for brain aging and for health. In a recent MRI study of the relations between personality and regional brain volume in individuals between 44 and 88 years of age, individuals who scored high in the personality trait of neuroticism from the NEO Personality Inventory showed smaller volumes of gray matter in the frontal and medial temporal regions and greater age-related decreases in regional volume. Further, individuals who scored high in the personality trait of conscientiousness from the NEO Personality Inventory showed higher volumes of gray matter and less decline in regional volume (Jackson et al., 2011). These findings suggest that the personality attributes of neuroticism and conscientiousness moderate age-related cross-sectional decline in the prefrontal and medial temporal regions of the brain.

Developmental studies of health–personality relations have found that mortality risk is lower for individuals who score high on conscientiousness and that mortality risk is higher for individuals who score high on neuroticism. Further, it is well-known that personality traits affect maintenance of health-promoting behavior (dietary behavior, exercise), and have consequences for physical health outcomes, including cardiovascular disease, elevated blood pressure, diabetes, and mortality.

In describing the relations between personality and brain aging, it is important to recognize that the brain is the central mediator of ongoing, system-wide physiological adaptation to environmental challenges (e.g., see Ganzel et al., 2010). Indeed, the healthy brain is dynamically adaptive in mediating between ongoing environmental challenges and the biological self, and in regulating the neurophysiological consequences of prolonged and acute stress.

Conclusions

Age-related changes in behavior, cognition, and personality during adult years and in later life depend on the dynamic interplay between brain aging mechanisms and behavioral factors (i.e., learning, regularly occurring adaptive organism–environment transactions). Age-related losses occur for many aspects of brain aging, but there is also growth and stability for some aspects of brain function throughout life. Concepts of brain plasticity and brain reserve capacity give emphasis to the potential of individuals to continue to improve, maintain, or optimize behavioral function in response to insidious losses associated with normal aging, and to relatively abrupt losses associated with disease.

Brain and Behavioral Lateralization in Animals

Lesley J Rogers, School of Science and Technology, University of New England, Armidale, NSW, Australia

Abstract

Differential control of behavior and information processing by the left and right hemispheres of the brain is now well known to be characteristic of a wide number of vertebrate species, thus overturning the long-held myth that it is unique to humans. Perhaps, even more unexpected has been the discovery that the pattern of lateralization in vertebrate species is fundamentally the same as that in humans. Research on animals is revealing important information about the development, evolution, causation, and function of this key aspect of brain organization.

Definition of Lateralization

Lateralization refers to left–right structural or functional differences. Structural differences may be present between the left and right sides of the body or the brain. Here, the focus is on left–right differences in brain and behavior. In other words, the question addressed is whether the left and right sides of the brain control different functions and process information in different ways. Such side differences in behavior may exist without apparent, or known, differences in structure.

Within a population or species lateralization may be present in two ways: at the individual or population level. Individual-level lateralization refers to examples in which most, if not all, individuals show lateral biases but the number biased to the left is the same as the number biased to the right. Population-level lateralization refers to directional bias in which the majority of animals are biased in the same direction.

History

Lateralization used to be considered a unique characteristic of the human brain, and therefore a specialization making us different from, and superior to, all other animals. This view was held for over a century, ever since the discovery in the 1860s of lateralization in humans. Particular importance was made of the left hemisphere's specialization for speech and language and the right-hand preference for fine manipulation required in using tools and writing (Corballis, 1991).

In the 1970s and 1980s, the misconception of human exclusiveness in this characteristic was laid bare by the discovery of functional lateralization in avian and rodent species. In a songbird species, it was shown that control of singing is a function of the higher vocal center in the left hemisphere but not by the equivalent area in the right hemisphere (Nottebohm et al., 1976). In domestic chicks, it was shown that the left but not the right hemisphere is used when searching for grains made difficult to find by scattering them among pebbles of similar shapes, sizes and colors, and adhered to the floor (Rogers and Anson, 1979). The same study also found that the left hemisphere is used in auditory habituation learning. In rats, hemispheric differences were shown for control of activity in the open field (Denenberg et al., 1978) and the right hemisphere was found to be specialized for control of spatial and affective (emotional) behavior (Denenberg, 1981, 1984). These examples of lateralization were all directional biases present at the population level.

Since these initial discoveries, the field of lateralization in vertebrate species has expanded with increasing rapidity and it is now clear that lateralization of brain and behavior is widespread among vertebrate species and expressed in a broad spectrum of behavior (Rogers and Andrew, 2002; Rogers et al., 2013b). It has even been revealed recently in some invertebrate species (see below). Among the vertebrates, certain species have emerged as models for studying the development and nature of lateralization of brain and behavior: these model species include the domestic chicken, the domestic pigeon, and the zebra fish (Halpern et al., 2005). Among the invertebrates, model species used to investigate lateralization include the nematode *Caenorhabditis elegans* (Hobert, 2014) and, as a recent addition, honeybees (see below).

Until about a decade ago, researchers working on lateralization in humans had been reluctant to accept the presence of lateralization of brain and behavior in nonhuman species but that is no longer the case. Some researchers still argue that lateralization of the brain is stronger in humans than in any other species but this view is, in essence, simply a broadening of the originally held belief of human exclusiveness of laterality and no evidence supports it. On the contrary, the footedness of some species of cockatoos is as strong as, or even stronger than, the right-hand preference of humans (Harris, 1989; Rogers, 1980) and just as many brain functions are known to be lateralized in birds, for example, as is the case in humans (Rogers, 2008).

Methods of Revealing Lateralization

These early examples of lateralization were shown by unihemispheric placement of lesions in songbirds (e.g., canaries), ablation of one or the other hemisphere in rats and, in chickens, unihemispheric administration of pharmacological agents that impair neural function or development (e.g., cycloheximide or glutamate). Behavior of animals with treatment of the left hemisphere was compared to that of animals with the right hemisphere treated in the same way. Following this early work, it was found that lateralization could be demonstrated in species with their eyes positioned on the sides

of their head simply by putting a patch over one or the other eye and testing their behavioral performance. This procedure reveals functional differences between the hemispheres because, in these species, input from one eye is processed mainly by the opposite side of the brain. The first use of the monocular technique, by Mench and Andrew (1986), confirmed the role of the left hemisphere (right eye) in chicks searching for grain on a background of distracting pebbles. Eye patching has become a standard technique for showing visual lateralization, and it has been used especially in domestic chicks (research summarized in Rogers et al., 2013b). Eye patching does not reveal visual lateralization in species with their eyes positioned frontally (i.e., with a large binocular field of vision) because their visual input, except that from the extreme left or right sides of the visual field, goes from each eye to both sides of the brain. In these species, as in humans, presentation of stimuli in the extreme left or right visual field can reveal lateralization and this has been used in the laboratory to test primates after sectioning of the commissure that connects the left and right hemispheres, known as split-brain preparations (Hamilton and Vermeire, 1988).

Another technique now used widely is to compare responses to stimuli seen in the left monocular visual field with responses to those seen in the right monocular visual field. Toads, for example, react more strongly to a model predator (mimicking an advancing snake) seen in their left monocular visual field than they do to the same stimulus seen in their right monocular visual field (Lippolis et al., 2002) and this asymmetry has also been shown in marsupial dunnarts (Lippolis et al., 2005) and horses (Austin and Rogers, 2007). Stronger aggressive and sexual responses are directed toward conspecifics seen on an individual's left side, as found in a number of species, including birds, lizards, frogs, baboons, and feral horses (summarized in Rogers, 2002; for evidence in horses see Austin and Rogers, 2012).

A variation on the latter way of revealing lateralization is to record head turning and the eye used to look at particular stimuli. As an example of the latter, lizards turn their head so that they can use their left eye to view a potential predator approaching from behind (Bonati et al., 2010) and Australian magpies tilt their head to look upward with the left eye to see aerial predators (Kaplan and Rogers, 2013). This method has excellent application in field studies of species with lateral eyes.

Measuring hand or limb preferences are other ways in which researchers have attempted to determine whether or not a species is lateralized. Determining whether primates show handedness has been of particular interest, stemming from a desire to see whether our closest relatives might show right-handedness, as do humans. The first reports appeared to confirm the uniqueness of humans in this respect: primates were seen to have individual hand preferences, which could have been acquired through practice, but no directional biases within species (Warren, 1980). However, since the data collected were rather piece-meal and published in a variety of journals, there was a need to examine it more comprehensively and in doing so MacNeilage et al. (1987) found convincing evidence that primates do show hand preferences as directional biases. Lower primates (prosimians) show left-hand preferences for capturing insects and grasping food while they support their body using the right hand. As postulated by the Postural Origins Theory, this shifted to right hand preference for manipulation of objects as primates evolved to become more bipedal and the right hand was less needed to support the body, culminating in the right-handedness of humans (MacNeilage et al., 1987). At first there was much controversy about whether or not chimpanzees are right-handed but more recent evidence from larger samples shows that they do have a significant preference to use the right hand when using tools or in bimanual coordination (Hopkins et al., 2004, 2011).

Although population bias of limb preference shows brain lateralization of motor control, its absence in a species does not mean that brain lateralization for perceptual processing is absent (explored further in Rogers, 2009). Indeed, the early evidence for brain lateralization in rats (discussed above) came at a time when it was known that individual rats had paw preferences but they had no directional bias at the population level to use the same preferred paw to reach for and grasp food items (summarized in chapter 3 of Bradshaw and Rogers, 1993). Those working on primates took little to no cognizance of this evidence and continued to focus on measuring hand preferences as the assumed marker of brain lateralization. For this reason, the battle about human uniqueness continued for longer than it might have done so had researchers considered the evidence for limb preferences in species other than primates.

Lateralization of brain activity can be revealed by using radioactive tags that reflect increased blood flow or early gene expression in regions of the left and right hemispheres. Since these techniques require killing of the animals followed by sectioning of their brain, functional magnetic resonance imaging of the brains of living animals is a preferred method of revealing lateralization. It is a recent development among the techniques used to study lateralization in animals. For example, it has been used to examine regional activity of the chimpanzee cortex during communicative signaling. In fact, a bias to use regions of the left hemisphere (e.g., the left inferior frontal gyrus) suggests that chimpanzees may possess neural precursors of human language (Taglialatela et al., 2008). As imagining techniques become more widely available, they are bound to become an important method of studying animal brain function, including lateralization.

Pattern of Lateralization in Vertebrates

The pattern of specialization of the left and right hemispheres of vertebrates is broadly similar across species and remarkably similar to that present in humans (summarized by MacNeilage et al., 2009; Rogers et al., 2013b; **Figure 1**). The left hemisphere is specialized to categorize objects and other stimuli, and to control learned or well-practiced behavior when the animal is in a relaxed state. It also focuses attention on particular features of objects or aspects of the environment. Use of the left hemisphere occurs when the animal has to sustain responses, as in pursuing prey or searching for food (e.g., chicks searching for grains, discussed above). It is used when choices have to be made according to categories, such as food type or preferred type of partner, as shown in male zebra finches by Templeton

Figure 1 Summary of the different functions of the left and right hemispheres, as determined by testing a range of vertebrate species. The arrows link functions that may be related.

et al. (2014). (Note that use of the right eye and left hemisphere is expressed during *choice* between potential partners but that the right hemisphere controls the actual act of copulation.)

The right hemisphere is specialized for controlling rapid responses given in emergency situations, including attention to and escape from predators. It has a broad, global attention important in detecting novel stimuli. It assesses multiple properties of objects and the surrounding environment. The right hemisphere also processes spatial information relying on geometric cues, recognizes faces, and controls the expression of emotions, particularly of fear and aggression.

As an example, the dichotomy of hemispheric function was illustrated by testing chicks on their spatial ability used to find hidden food (Tommasi and Vallortigara, 2001): when the left eye was occluded (using the right eye and left hemisphere) chicks relied on landmarks to find the food and when the right eye was occluded (using the left eye and right hemisphere) they used geometrical cues (i.e., metric properties such as direction and distance from walls of an arena). Rats have also been shown to use the right hemisphere and left eye for spatial navigation (Cowell et al., 1997).

Humans show similar use of the right hemisphere for processing global patterns of information and the left for attention to detail (summarized in MacNeilage et al., 2009). Faces are also processed in the right hemisphere in humans and animals, as shown clearly in sheep by left visual hemifield superiority in discriminating faces of other sheep (Peirce and Kendrick, 2002). Chicks show a similar specialization of the right hemisphere in that they can discriminate between social companions when they use their right hemisphere but not when they use their left hemisphere (Vallortigara and Andrew, 1994) and the right hemisphere is used in establishing hierarchies, as needed to form their species-typical social order (Daisley et al., 2009).

As in humans, emotions, particularly strong negative ones, are controlled by the right hemisphere. Rats, for example, rely on the right hemisphere to learn the fear response required for aversion of particular tastes (Denenberg et al., 1980). Chicks also express higher levels of emotion when they view fear-inducing stimuli with their left eye (right hemisphere) than they do when they view the same stimuli with their right eye (Andrew, 1983) and a similar right-hemisphere bias to respond more strongly to fear-inducing stimuli has been shown in dogs for stimuli they see (Siniscalchi et al., 2010), those that they hear (Siniscalchi et al., 2008) and those that they smell (Siniscalchi et al., 2011).

The strong negative emotions expressed by the right hemisphere can be suppressed by the left hemisphere, and this is needed to allow pursuit of prey without distraction of attention. In mammals, this suppression of the right by the left hemisphere is affected via the corpus callosum, a set of connections between the hemispheres. In other species it is mediated via commissures, some of which occur at levels of brain organization below the hemispheres (e.g., the tectal and posterior commissures of birds).

It is important to note the popular concept of 'left-brained' or 'right-brained' individuals is incorrect. Both hemispheres are in communication with each other and the balance of control can change frequently depending on external circumstances and internal states. Although individuals might show a trend toward using one hemisphere more often than the other, this is not an exclusive bias.

Evolution of Lateralization in Vertebrates

Lateralization of behavior was already present in the earliest vertebrates (Andrew, 2002; summarized in Rogers et al., 2013b). Ancestral chordates were structurally asymmetrical. An organism still living today, the lancelet, *Branchiostoma*, provides a key to early vertebrate evolution. Its larval form has its mouth located asymmetrically on the left side and the associated structures in the nervous system used for feeding and controlling the mouth are also on the left side. Although asymmetry is no longer present in adult lancelets, the asymmetry of the larval stages seems to have been key to the evolution of lateralization in vertebrates.

As vertebrates evolved, they acquired paired eyes and these eyes, it seems, had differently specialized functions (see chapter 3 in Rogers et al., 2013b): the left side of the brain continued to control detection and capturing of prey and this meant specialization of the right eye to perform this behavior since the right eye sends its inputs to the left side of the brain.

The general pattern of lateralization was already present in early vertebrates and it was conserved throughout vertebrate evolution. Although some substantial modifications may have taken place during the evolution of brain laterality, it was already a firmly established characteristic of the vertebrate brain well before humans evolved. In other words, lateralization in animals was a precursor to the hemispheric specializations of humans (MacNeilage, 2008; MacNeilage et al., 2009). Specialization of the left hemisphere for language and speech in humans seems to be an elaboration of this hemisphere's superiority in sequential processing (Bradshaw and Nettleton, 1981) and for communication, present well before humans evolved (MacNeilage et al., 2009; Meunier et al., 2013; Meguerditchian et al., 2013). Furthermore, it seems that dominance of the left hemisphere for gestural communication was followed by the addition of vocal control and thence to speech and language.

Lateralization in Invertebrates

Recently, researchers have begun to look for evidence of lateralization in invertebrates and some convincing examples are coming to light (reviewed by Frasnelli et al., 2012). In bees, for example, the left and right antennae have different roles in learning and recall of olfactory associations. First, honeybees were found to be able to learn to associate a particular odor with a sugar reward provided they used their right antenna but not when they used their left antenna (Letzkus et al., 2006). Recall of such a memory is initially dependent on the right antenna but then, after a few hours, the memory can be recalled only if the left antenna is used (Rogers and Vallortigara, 2008). The same lateralized access to memory has been shown in other social bees but not in a solitary species of bee (summarized in Frasnelli et al., 2014). This social versus nonsocial difference in lateralization at the population level is consistent with the hypothesis about directional bias and social behavior discussed further below.

Structural asymmetry in the brain also determines the ability of fruit flies, *Drosophila*, to form long-term memories (Pascual et al., 2004). Transition of memory from short- to long-term in this species depends on a structure usually present only in the right side of the brain and close to the region linking the left and right sides of the brain. Some fruit flies have a duplicate of this structure in the left side of their brain (i.e., they are symmetrical) and they are unable to make long-term memories.

Squids provide another example of lateralized behavior in invertebrate species. *Sepia officinalis* uses its left eye to guide escape swimming (Jozet-Alves et al., 2012). It is not known whether the deep-sea squid *Histioteuthis* has the same lateralization of behavior but marked asymmetry in the structure of its eyes would suggest so: the left eye is large and looks upward, presumably to detect predators, and the smaller right eye looks downward, presumably for prey (see Rogers et al., 2013b).

Whether lateralization in invertebrate species is in any way related to lateralized brain function in vertebrates is not known at this time. However, evidence of its presence has opened up new avenues of research on evolution and factors influencing development of lateralization (see Halpern et al., 2014). It remains possible that lateralization in invertebrates evolved quite independently of that in vertebrates but, regardless of whether or not this is the case, evidence suggests that invertebrate brains also benefit from being lateralized.

Development of Lateralization in Vertebrates

Early studies by Collins (1985) on paw preferences in mice demonstrated that, through genetic selection, it is possible to alter the strength of paw preference but not its direction (i.e., whether individuals prefer to use the left or right paw to reach into a tube to obtain food). Other behavioral lateralities appear to be partly genetically determined and partly influenced by environmental factors. In birds, for example, exposure of the eggs to light leads to lateralization of the visual pathways and of visual behavior (summarized by Rogers, 2008). This was shown first in chickens and later in pigeons. In the final stages of incubation avian embryos are positioned in the egg so that their right eye is next to the shell and can be stimulated by light, whereas their left eye is occluded by the embryo's body, thereby preventing light from reaching it. This asymmetry of stimulation by light before hatching initiates the development of visual lateralization. Embryos hatched from eggs incubated in the dark lack visual lateralization (chickens, Rogers, 1982; pigeons, Güntürkün, 2002). As little as 2 h of light exposure of chick embryos during the final days before hatching, when the visual system is becoming functional, is sufficient to generate visual lateralization (Rogers, 1990). In the pigeon, visual lateralization caused by this early effect of light persists into adulthood and it involves connections both to and from the forebrain (Valencia-Alfonso et al., 2009). In chicks, it is known that the effect lasts for the first 3 weeks of life but no studies have examined whether or not it persists in to adulthood. It should be noted, however, that light exposure of the embryo affects lateralization in different pathways of the visual system in chickens and pigeons although the outcome in behavior is quite similar in both species (Deng and Rogers, 2002; Manns and Güntürkün, 2009). Exposure to light during embryonic development also affects communication between the hemispheres (Manns and Römling, 2012).

Light stimulation also has a critical effect on the development of visual lateralization in zebra fish but, in this case, the influence of light occurs earlier in development. Zebra fish fry hatched from eggs exposed to the normal light/dark cycle show lateralization of avoiding a model predator presented on their left side and approaching it when presented on their right side, whereas fry raised in the dark do not show this asymmetry (Budaev and Andrew, 2009). This effect of light differs from that seen in birds because the zebra fish's eyes are not even functional at this early stage of development. Instead, light may activate particular genes important in the development of lateralization. Alternatively, the light-sensitive parapineal organs, which are known to be

asymmetrical in zebra fish (Halpern et al., 2003), may be involved (Budaev and Andrew, 2009).

Development of lateralization in sensory systems other than vision might also be affected by experience in early life but there has been very little research in this area. One example is, however, available and that concerns laterality of behavior in the cuttlefish, *Sepia officinalis*. Laterality in this species is enhanced by exposure of the eggs to the odor of a predator, that of the sea bass (Jozet-Alves and Hérbert, 2013). There is also recent evidence that changing carbon dioxide levels of the sea can affect lateralized turning behavior in a species of coral-reef fish (Domenici et al., 2014): it reverses the direction of lateralization. The relevance of this to potential effects of climate change on behavior deserves further research.

Steroid hormones also play a role in the development of lateralization and one way in which they might achieve this is by interacting with the effects of light on lateralization. Injecting estrogen, testosterone, or corticosterone into the developing egg nullifies the effect of light exposure on lateralization (Rogers and Rajendra, 1993). Whether or not similar processes operate in other species and whether they have any relation to sex differences in lateralization has not yet been investigated, although sex differences in lateralization have been documented in both animals and humans (discussed by Pfannkuche et al., 2009) and frequent claims are made about sex hormones determining these.

Function of Lateralization

Lateralized behavior has been shown in wild animals. Wild black-winged stilts peck at prey on their right side (using the right eye) and show copulatory behavior to conspecifics seen on their left side (Ventolini et al., 2005). Wild Australian magpies view a predator with the left eye before they withdraw from it (Koboroff et al., 2008) and wild horses view with the left eye before they attack (Austin and Rogers, 2012). Wild beluga whales show a preference to have their calf on their left side (right hemisphere) (Karenina et al., 2010). These and other examples show that lateralization of behavior is not simply an inconsequential aspect of brain function revealed only by testing animals in the laboratory. Since it is not obligatory that asymmetries of brain anatomy or neurochemistry will be expressed as side biases in behavior (i.e., they could be masked), these manifestations of laterality in natural behavior are important. They raise intriguing issues about the advantages and disadvantages of being lateralized.

Clearly it must be disadvantageous to have side biases in response to predators since predators may approach on either side and even a slight difference in speed of detection or response could have consequences for survival. Likewise, a similar argument could be made for side biases in responding to prey or other food items. Therefore, it seems logical to expect that these disadvantageous side biases are counterbalanced by advantages of another kind.

By comparing the behavior of animals with and without lateralization, it has been possible to determine some of the benefits of having a lateralized brain. The chick is an excellent model for testing this since visual lateralization can be modified by light exposure before hatching.

One of the hypothesized advantages of having a lateralized brain is to increase cognitive capacity and this might be manifested as more success in performing two or more tasks simultaneously. Results obtained by comparison of chicks with and without visual lateralization support this hypothesis. Chicks hatched from eggs exposed to light are able to monitor overhead for predators (right hemisphere) while they are searching for food (left hemisphere), whereas chicks hatched from eggs incubated in the dark are unable to do this (Rogers et al., 2004). The latter are less likely to detect the predator (a silhouette of an eagle moving overhead) and, when they do see it, they are so distracted by it that they are unable to find food scattered on a background of pebbles. A similar result has been obtained using a species of fish faced with capturing prey while a predatory fish watched on: fish with stronger lateralization performed more efficiently than those with weak lateralization (Dadda and Bisazza, 2006).

Pigeons too perform better in finding food among distracting grit (pebbles) when they are more strongly lateralized (Güntürkün et al., 2000): there is a positive correlation between strength of lateralization and success in pecking at grain. In chimpanzees, stronger hand preference is associated with more efficient 'fishing' for termites by inserting a piece of grass into the termite mound, although in this case the direction of hand preference is irrelevant (McGrew and Marchant, 1999). In line with this finding, a study of Australian parrots has reported that those with stronger lateralization, measured by foot preference for holding food, have better ability to solve cognitive problems (Magat and Brown, 2009).

These results provide evidence of cognitive advantage of individuals being lateralized but they do not explain why the majority of individuals are lateralized in the same direction. This seems to have something to do with social behavior. When a lateralized animal interacts with another, it could be advantageous if they are both lateralized in the same direction (Vallortigara and Rogers, 2005). Stable social hierarchies in chicks depend on this: groups of lateralized chicks form more stable hierarchies than do groups of chicks not so lateralized (Rogers and Workman, 1989).

Highly social honeybees show lateralization of social behavior (Rogers et al., 2013a). When honeybees are put in pairs in containers they may contact in positive social interaction, which includes proboscis extension, or negative social interaction, which includes C-responses as used in stinging. After removal of their left antennae, pairs of bees perform appropriate social behavior (i.e., proboscis extension if they are from the same hive and C-responses if they are from different hives). Pairing of bees after removal of their right antennae leads to inappropriate social behavior: same-hive pairs are slow to contact and they perform more C-responses and fewer proboscis extension responses. This finding demonstrates the importance of population-level lateralization in social behavior.

Conclusion

Lateralization of brain and behavior is widespread among vertebrate species and it is also present in invertebrates. Hence,

it does not depend on brain size or the overall neural capacity of a species and seems to be beneficial to all, or most, brains, possibly by enhancing the ability of individuals within a species to solve problems, form memories, and to perform more than one task simultaneously. In essence, it allows parallel processing of incompatible tasks requiring very different neural processing.

The left hemisphere is specialized to focus attention and categorize stimuli, such as required in choosing food (prey). The right hemisphere is used in emergency situations when rapid responses are required and it has a special role in stress responses, expression of intense emotions, and detection of novelty.

Individual- and population-level lateralization can be generated or modulated by experience in early life. Evidence for this comes mainly from research on avian embryos and in the visual modality. However, a limited number of examples, in mammals and for other sensory modalities indicate that sensory input may influence lateralization more generally. This provides a means by which lateralization might be adapted to specific environmental conditions. Stress in early life might, for example, influence the development of lateralization either directly by changing the embryo's hormone levels or indirectly by altering maternal behavior (e.g., by varying the amount of light exposure during a sensitive period of visual development).

Now that the idea of brain lateralization as a trait only of humans has been disproven, research is increasingly using animal models to address questions about the development, causation, function, and evolution of lateralization. This has implications for understanding not only animal behavior but also human behavior, particularly in cases of dysfunction that seem to be associated with reduced or reversed lateralization (e.g., depression, autism, or dyslexia).

This article is a revision of the previous edition article by E. Zaidel, volume 2, pp. 1321–1329, © 2001, Elsevier Ltd.

Abstract

Structural and functional asymmetries between the left and the right hemisphere of the brain are ubiquitous in the vertebrate brain. In this article, a general introduction into brain asymmetry is given, followed by a discussion of handedness and other forms of behavioral preferences. Moreover, cognitive domains for which brain asymmetry has been reported are described in addition to structural brain asymmetries. The ontogenesis of brain asymmetry as well as the advantages of having an asymmetric brain is discussed. The article concludes with a description of factors modulating brain asymmetry, most notably sex and pathological processes.

Definition of the Term

The term brain asymmetry refers to structural, functional, or physiological asymmetries between the left and the right hemisphere of the brain. The hemisphere in which the relevant parts of the brain are relatively larger, superior in performance, or more active during a given task is called dominant. Brain asymmetry is a continuous phenomenon, with considerable interindividual differences in strength and direction, and it is common that for a given function or structure, a minority of individuals show the so-called atypical asymmetry (Van der Haegen et al., 2013), that is, a reversal of the direction of the asymmetry found on population level. This phenomenon can either be due to cortical reorganization processes after pathological events or due to an ontogenetic predisposition. It is also important to note that brain asymmetry is usually relative: While one hemisphere is more active or superior in performance than the other, it does not indicate that the subdominant hemisphere is not active at all. Essentially, three forms of brain asymmetry can be distinguished (Palmer, 1996; Vallortigara et al., 1999):

1. Absence of asymmetry (sometimes also called symmetry): All or most members of the population do not show a left- or right-hemispheric dominance.
2. Individual-level asymmetry (sometimes also called antisymmetry): Some individuals show a significant left-hemispheric dominance while others a significant right-hemispheric dominance, but there is no significant asymmetry at the population level.
3. Population-level asymmetry (sometimes also called directional asymmetry): The majority of the population shows a hemispheric dominance to one side.

While brain asymmetry has initially been discovered in humans and was thought to be uniquely human for several decades, it is now considered a general principle of vertebrate brain organization (Ocklenburg and Güntürkün, 2012; Rogers, 2009) and has been reported in dozens of different vertebrate species (Bisazza et al., 1998; Halpern et al., 2005; Ocklenburg et al., 2013b). Notable examples for non-human asymmetries have been found in the songbird song system (George, 2010), the zebrafish habenula (Bianco and Wilson, 2009), as well as in the visual systems of chickens (Rogers, 1996), and pigeons (Manns and Güntürkün, 2009). Interestingly, left–right asymmetries of behavior and nervous system have recently also been shown in several invertebrate species, e.g., honey bees, ants, and octopuses (Frasnelli et al., 2012).

The scientific interest in hemispheric asymmetries started with a seminal discovery by a French physician called Pierre Paul Broca, who published about a patient called Monsieur Tan because the only word he was able to utter was 'tan' (Broca, 1861). Postmortem analysis of the brain of this massively speech-impaired patient revealed a lesion in the left frontal lobe, demonstrating that the left hemisphere and especially an area in the left posterior inferior frontal gyrus now known as Broca's area is highly relevant for language production. After Broca's initial discovery, a dominance of the left hemisphere for many aspects of speech production and perception was demonstrated by several researchers. However, it was unclear for a long time whether the right hemisphere had any complementary specialization, until it was shown that in most individuals it is dominant for several aspects of spatial processing (Vogel et al., 2003). Subsequently, several different functional and structural asymmetries have been identified in humans and other vertebrates, all of which are discussed in this article. Starting in the 1960s, research in split brain patients and callosotomized animal models allowed for deeper insights into complementary hemispheric specialization and how the disconnected cerebral hemispheres work independently of each other (e.g., Sperry, 1961; Gazzaniga, 2005; *see* Split Brains and Human Consciousness for further details). These experiments in turn gave new impulses to asymmetry research in healthy participants, which, over the last decades, has been conducted with an impressive array of different neuroscientific approaches. Today, identifying the molecular and neurophysiologic mechanisms underlying brain asymmetry remains one of the key questions of modern cognitive neuroscience. Cerebral specialization has been reported for a large number of vertebrate brain structures and functions, ranging from basic perceptual systems in invertebrates (Hobert et al., 2002) to several higher cognitive functions in humans (Corballis, 2012). This article will focus

on these functional domains, as well as on the different techniques used to investigate lateralization within these cognitive systems and relevant brain structures and the phylogenetic and ontogenetic mechanisms underlying its development.

Handedness and Other Forms of Behavioral Preferences

The probably most salient form of brain asymmetry in everyday life is left- or right-handedness. About 90% of the population is right-handed, while the remaining 10% is left-handed (Grimshaw and Wilson, 2013), making human handedness the most pronounced behavioral left–right preference in vertebrates. This clear population-level asymmetry in hand use is not paralleled by any distinct morphological asymmetries between the two hands. This indicates that handedness is a manifestation of varying skills between the two hands and reflects a brain asymmetry in the motor cortex (Corballis, 2009). The easiest methodological approach to determine an individual's handedness is a dichotomous differentiation between left- and right-handers based on an assessment of hand preference for writing or drawing. However, this method can lead to erroneous results under some conditions, e.g., if left-handers who have been forced to learn to write with the right hand are assessed (Klöppel et al., 2010). Thus, several other methods to assess handedness have been developed, including observational methods (Bryden et al., 2007), assessment of handwriting speed (Provins and Magliaro, 1993), the pegboard test (Annett, 2002), as well as a number of different questionnaires that assess hand use during different activities (e.g., Annett, 1970; Bryden, 1977; Crovitz and Zener, 1962; Oldfield, 1971; Peters and Servos, 1989; Siefer et al., 2003). The most frequently used of these instruments is the Edinburgh Handedness Inventory (EHI) (Oldfield, 1971), a 10-item questionnaire, in which participants have to indicate their preferred hand for different everyday activities (e.g., writing, drawing, throwing, and striking a match). Based on the subjects' answers, a laterality quotient (LQ) ranging between −100 (consistently left handed) and +100 (consistently right handed) can be calculated, with positive values indicating a right-sided preference and negative values a left-sided preference. Based on the individual LQ values, subjects can then be grouped into different categories, e.g., subjects with an LQ larger than zero are considered right handed and participants with an LQ smaller than zero are considered left handed. Besides this simple model, there are also different categorization schemes in which subjects with intermediate LQ values are considered inconsistently handed or ambidextrous (e.g., Isaacs et al., 2006; Tzourio-Mazoyer et al., 2010). While humans show a clear population-level asymmetry in handedness, the situation is less clear for non-human primates. Great apes exhibit individual-level asymmetry in handedness and evidence for population-level asymmetries has been reported by several studies (Hopkins, 2006; Hopkins and Cantalupo, 2005; Hopkins et al., 2011) but there is also evidence arguing against this view (McGrew and Marchant, 2001; Palmer, 2002). These contradicting results indicate that handedness in primates is modulated by environmental factors to a larger extent than is human handedness (Ströckens et al., 2013).

In addition to handedness, behavioral preferences have also been identified for several other motor and sensory systems. For all of these, the majority of the population exhibit a right-sided preference, but typically with a somewhat lower rate than the 90% observed for handedness. For example, infants show a preference to turn their head to the right relative to their body (Hopkins et al., 1987; Ververs et al., 1994), and a right-sided head turning preference can also be observed in adults, e.g., during kissing (Güntürkün, 2003; Ocklenburg and Güntürkün, 2009). Moreover, approximately 80% of amateur soccer players show a preference to use the right foot when kicking the ball (Carey et al., 2009). This preference called footedness can be quantitatively assessed using the Waterloo Footedness Questionnaire (Elias and Bryden, 1998; Elias et al., 1998), a short questionnaire that allows for the calculation of an LQ similar to the EHI.

In addition to motor preferences as handedness or footedness, preferences in the usage of sensory organs have been observed for eyes and ears. For example, ear preference can be assessed by asking which ear an individual would use when listening to a conversation going on behind a closed door and it has been shown that about 65% of the population preferably uses the right ear in this context (Reiss and Reiss, 1999). A similar distribution has also been observed for eye preference which can be assessed by asking subjects to indicate which eye they would prefer when looking through a keyhole. Here, it has been reported that about 66% of the population prefer the right eye for this and similar activities (Reiss and Reiss, 1997). The question whether the different motor and sensory preferences have a common ontogenetic background, or not, has not been answered unequivocally. While some studies report strong positive correlations between handedness, footedness, ear preference, and eye preference (Dittmar, 2002), others only found an association between handedness and footedness, but do no significant association with lateral preference for eye or ear use suggesting that the ontogenesis of lateral preference in sensory and motor systems may at least partly rely on independent processes (Reiss et al., 1999).

Apart from this left–right biases in the use of bilaterally paired motor or sensory systems, several behavioral left–right preferences in interaction with the environment have been reported. For example, subjects tend to bump significantly more often into the right than into the left side of a narrow doorway when walking through it (Nicholls et al., 2007) or using an electric wheelchair to drive through it (Nicholls et al., 2010). Moreover, healthy subjects show a right-sided seating preference in cinemas (Karev, 2000).

Functional Hemispheric Asymmetries

The Left Hemisphere

While there are parts of language processing that are conducted by the right hemisphere (e.g., paralinguistic aspects; Lindell, 2006), most aspects of speech production and perception are mediated by the left hemisphere. Since Broca's initial discovery, several different methods have been applied to

determine the language-dominant hemisphere. For example, anesthesia of the left hemisphere by injecting sodium amorbital into the left carotid artery (a procedure called Wada test; Baxendale, 2009) leads to severe language production impairments in most subjects, thus indicating a language dominance of the left hemisphere just like in Broca's patient. However, since this procedure is too invasive to be used in basic research, several other methods have been developed to determine the language-dominant hemisphere. One of the most widely used behavioral tasks to do so is the dichotic listening technique (Kimura, 2011; Tervaniemi and Hugdahl, 2003; *see* Dichotic Listening and Language: Historical Review for an in-depth discussion of this paradigm). In this experimental paradigm, subjects wear headphones and two auditory stimuli (e.g., meaningless syllables like 'ba' or 'ga' or words) are presented simultaneously, one to the left and the other one to the right ear. Subjects are instructed to indicate (e.g., by pressing a button or by verbal response) which stimulus they heard. Most individuals report the stimulus that was presented to the right ear more often than the one that was presented to the left ear (the so-called right ear advantage), which is thought to reflect a dominance of the left hemisphere for the processing of verbal stimuli (Bryden, 1988). Another commonly used behavioral performance measure to determine brain asymmetry is the visual half-field technique. This method is based on the principle that visual input from the right visual hemifield is processed by the left hemisphere, while input from the left visual hemifield is processed by the right hemisphere (Kolb and Whishaw, 2003). By presenting stimuli tachistoscopically (very briefly, e.g., less than 200 ms) either within the right or the left visual hemifield it is ensured that the stimulus is only processed by the contralateral hemisphere, and that no interhemispheric transfer via the corpus callosum occurs during this process. Paradigms utilizing this technique have been developed for several different types of asymmetrically processed visual stimuli (e.g., spatial stimuli and faces). For example, language dominance can be determined using a lexical decision task. In this task, a word is presented in the center of the visual field, which is subsequently followed by another word presented either in the left or right visual hemifield. Subjects then have to indicate whether the two words were identical or not and on average a right visual field/left hemisphere advantage is observed (Hausmann and Güntürkün, 2000). In addition to behavioral paradigms, language dominance has been assessed with several different neuroimaging techniques. For example, a noninvasive and well-validated alternative to the Wada test is functional magnetic resonance imaging (fMRI) (Binder, 2011). Bethmann et al. (2007) recorded fMRI during a semantic language task and compared activations in several language-relevant regions of interest between the left and right hemisphere, including the inferior frontal sulcus, the inferior frontal gyrus, and the superior temporal sulcus. They observed stronger activations in the left compared to the right hemisphere in 92% of right-handers and similar numbers have also been obtained in studies measuring language lateralization with functional transcranial Doppler sonography during a word generation (Flöel et al., 2005; Knecht et al., 2000). Moreover, left-hemispheric language dominance has also been shown using electroencephalography (Sandmann et al., 2007) and magnetoencephalography (Della Penna et al., 2007). On the electrophysiological level, especially the N1 event-related potential (ERP) has been related to brain asymmetry for language. The N1 is the earliest ERP component reflecting recognition of verbal stimuli, and it has been found to be involved with the automatic lexical classification of words (Spironelli and Angrilli, 2009). In tasks using visually presented words as stimuli, a larger amplitude of the N1 has been observed for occipitotemporal brain areas in the left hemisphere than for the same areas in the right hemisphere (Spironelli and Angrilli, 2007).

The Right Hemisphere

The right hemisphere was considered being the 'inferior hemisphere' as recent as in the 1970s by some researchers (e.g., Lebrun, 1974), due to the fact that it was not clear whether it had any complementary specializations comparable to the left hemisphere's language dominance. Contrasting this view, a relative dominance of the right hemisphere has now been identified for a number of cognitive domains. For example, a strong right-hemispheric advantage has been reported for several visuospatial tasks (Vogel et al., 2003). On the behavioral level, brain asymmetry for visuospatial processing can be investigated with a figural comparison task using the visual half-field technique (Hausmann et al., 2002; Hausmann and Güntürkün, 1999, 2000). At the beginning of each trial, an irregular polygon is presented in the center of the visual field. Subsequently, a second stimulus is presented either in the left or right visual field. Subjects have to indicate whether the two stimuli were the same or not and on average a left visual field/right hemisphere advantage is observed in this task. In addition to behavioral indicators for a right-hemispheric dominance for spatial processing, fMRI studies indicate right-hemispheric brain activation asymmetries during spatial processing (Jansen et al., 2004) and spatial working memory (Nagel et al., 2013). Related to spatial processing is the pseudoneglect, the tendency of healthy subjects to exhibit a leftward bias when they are asked to mark the center of a horizontal line (the so-called line bisection task; Jewell and McCourt, 2000). This leftward bisection bias is thought to be due to right-hemispheric dominance for spatial processing which leads to a systematic overrepresentation of the left compared to the right visual half-field. A cognitive domain related to visuospatial processing for which a right-hemispheric dominance has consistently been found on the behavioral level is face processing (e.g., Godard and Fiori, 2010; Hausmann and Güntürkün, 1999). These findings are supported by neuroimaging studies that reported a stronger activation in the right fusiform face area compared to the same region in the left hemisphere during face recognition (Minnebusch et al., 2009; Rossion et al., 2000) as well as by electrophysiological studies investigating the N170, an ERP component related to face processing that shows higher amplitudes in the right hemisphere (George et al., 1996). Other cognitive domains for which a right-hemispheric dominance has been suggested include the perception of socially relevant stimuli (Brancucci et al., 2009), self-awareness, theory of mind and deception (Keenan et al.,

2005), as well as creative thinking (Mihov et al., 2010). Moreover, the processing of both positive and negative emotions (Borod et al., 1988; Demaree et al., 2005) or only negative emotions (Silberman and Weingartner, 1986) has been suggested to be cognitive functions with a right-hemispheric dominance.

Structural Brain Asymmetries

The scientific interest in structural brain asymmetries started with the seminal discovery that the left planum temporale, a region on the posterior surface of the temporal lobe which includes parts of Wernicke's area is considerably larger than the right one in the majority of the population (Geschwind and Levitsky, 1968). Three subtypes of structural brain asymmetries can be distinguished (for an overview see, Amunts, 2010): macroscopic asymmetries such as in shape or overall volume of a specific cortical area or pathway, microstructural asymmetries such as in the density or number of neurons within an area, and molecular asymmetries such as in gene expression. Besides the leftward asymmetry in the planum temporale, other macroscopic gray matter asymmetries have, for example, been observed in the Sylvian fissure, Heschls gyrus, Brocas area, as well as several sensory and motor regions, the limbic system, and several occipital and parietal areas involved in visuospatial processing (Amunts, 2010). Besides structural gray matter asymmetries, several left–right asymmetries in white matter pathways have been described (Catani, 2010). For example, relative fiber density of the arcuate fasciculus, a major white matter pathway that, besides other structures, connects Broca's and Wernicke's areas (Barrick et al., 2007), shows a pronounced leftward asymmetry in the most individuals. This leftward structural brain asymmetry was positively correlated with the strength of brain activation asymmetries during a verbal fluency task in right- but not left-handers (Vernooij et al., 2007) and has also been related to verbal recall ability (Catani et al., 2007). Another major pathway that has been found to be asymmetric is the uncinate fasciculus, a pathway connecting the anterior temporal lobe with inferior frontal cortex (Rodrigo et al., 2007; Yin et al., 2013); several more subtle structural asymmetries in smaller white matter pathways have also been reported (Barrick et al., 2007). On the molecular level, several genes that are asymmetrically expressed in the left and right hemispheres have been identified, such as LMO4 or DAPPER1 (Sun and Walsh, 2006). While the functional significance of this asymmetrical expression patterns is largely unclear, these genes constitute interesting candidate genes for different other forms of brain asymmetry.

Ontogenesis of Brain Asymmetry

The most advanced understanding on how brain asymmetry develops has probably been achieved in the zebrafish, in which a nodal signaling pathway has been identified that regulates neuroanatomical asymmetries in the habenular nuclei (Concha et al., 2000). In humans, both structural (Rentería, 2012) and functional asymmetries (Francks et al., 2007) are considered to be multifactorial brain phenotypes that are determined by several, possibly interacting, genetic and nongenetic factors. The vast majority of research on the ontogenesis of human brain asymmetry has been conducted regarding handedness. Genetic factors that have been related to handedness include the androgen receptor gene AR (Medland et al., 2005), LRRTM1 (Francks et al., 2007), and PCSK6 (Scerri et al., 2011). In addition, nongenetic factors like social modulation or perinatal asymmetrical perception induced by asymmetrical head position or parental care have been discussed to be relevant for individual handedness (Schaafsma et al., 2009). Apart from handedness not much research on the genetics base of other forms of brain asymmetry has been conducted, yet. There are two recent studies linking genetic variation in the *N*-methyl-D-aspartate receptor 2B subunit gene *GRIN2B* (Ocklenburg et al., 2011) and the cholecystokinin A receptor gene *CCKAR* (Ocklenburg et al., 2013a) to language lateralization measured with the dichotic listening task, but clearly a lot more research on the genetic and environmental factors determining language lateralization and all other forms of brain asymmetry is still needed.

Advantages of Brain Asymmetry

Since brain asymmetry is such a common phenomenon in vertebrates, several ideas regarding its evolutionary origin and advantage for survival have been brought forward. For example, Rogers et al. (2004) suggested that brain asymmetry is advantageous because it enhances the ability to perform two different tasks simultaneously. Also, a functional incompatibility between the logical demands associated with novelty detection and object categorization has been brought forward as a possible factor leading to brain asymmetry (Vallortigara et al., 1999), as well as an avoidance of unnecessary processing conflicts between the two hemispheres in general (Levy, 1969). Other suggested advantages include an increase in neural capacity due to an avoidance of unnecessary duplication of neural networks (Vallortigara, 2006) and the greater speed of uni- compared to bi-hemispheric processing since no interhemispheric transfer via the corpus callosum is needed (Ringo et al., 1994).

Brain Asymmetry and Sex

Various forms of brain asymmetries have been found to be sexually dimorphic, with several studies reporting that women are less lateralized then men (Draca, 2010). This sex difference is modulated by steroid hormones, as studies investigating brain asymmetry across the menstrual cycle reported that lateralization in naturally cycling women is decreased when the progesterone level is high (Hausmann et al., 2002; Hausmann and Güntürkün, 1999, 2000). Interestingly, a recent comprehensive analysis of over 1700 dichotic listening datasets (Hirnstein et al., 2013) reported that sex differences in language asymmetry as assessed by dichotic listening are age-dependent and rather small: While male

young adults showed greater asymmetry than female young adults, there were no sex differences in children and older adults. Also, this behavioral sex difference was not reflected by an fMRI activation asymmetry, as an analysis of a smaller sample of 104 dichotic listening fMRI datasets did not reveal any significant sex effects.

Brain Asymmetry and Pathology

Damage to corresponding regions in the left and the right hemispheres does not necessarily lead to the same detrimental effects. While left-hemispheric strokes often lead to language impairments, damage to the right hemisphere often leads to spatial and attentional deficits (Karnath and Rorden, 2012). Most notably, damage to the right perisylvan region leads to spatial neglect, a deficit in awareness of and attention toward the left side (Corbetta and Shulman, 2011; Karnath and Dieterich, 2006), a phenomenon that is only rarely observed after left-hemispheric strokes (Suchan and Karnath, 2011).

In a number of psychiatric or developmental disorders, atypical lateralization has been reported to be significantly more frequent than in the general population. For example, it has been reported that schizophrenic patients have – on average – a higher prevalence of non-right-handedness (Dragovic and Hammond, 2005) as well as reduced left-hemispheric language dominance (Collinson et al., 2009; Sommer et al., 2001), with the experience of positive symptoms and especially auditory hallucinations leading to a more pronounced reduction of the typical lateralization pattern (Ocklenburg et al., 2013c). In addition to schizophrenia, a greater frequency of atypical brain asymmetry has also been observed in autism or autism spectrum disorder (Knaus et al., 2010; Wan et al., 2012), attention deficit hyperactivity disorder (Shaw et al., 2009; Reid and Norvilitis, 2000), and dyslexia (Illingworth and Bishop, 2009).

Brain Damage: Neuropsychological Rehabilitation

Bryan D Fantie, American University, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

One of the most significant changes in neuropsychological rehabilitation over the last two decades has been its evolution from a field focused almost exclusively on cognitive and memory dysfunction to one that is holistic and that is concerned with entire human beings as multifaceted individuals, members of relationships, and responsive organisms trying to survive and flourish within complex environments. This article reviews briefly some of the major ideas and theories that gave rise to contemporary neuropsychological rehabilitation as well as recent advances and innovations, and challenges for the future of the field.

Definition

Advances in emergency medicine, biotechnology, computers, and, in particular, basic neuroscience, which has resulted, most notably, in an improved understanding of multiple forms of neural plasticity (see Kolb and Muhammad (2014) for a review), have fueled substantial developments in applied neuropsychology over the past few decades. These, and other contributions from the cognitive, social, and behavioral sciences, have not only led to dramatic changes in the way we conceptualize the fundamental functional nature of the human brain but have enriched the repertory of tools and techniques available to ameliorate the effects of brain damage.

For centuries, people thought of the brain as a magnificent, logical, thinking machine, allowing us to solve mathematical problems and do things such as physics and architecture. The current zeitgeist, however, is based on the notion that the evolutionary pressure related to the need to make sense of both our often infuriatingly complex emotional lives and our large and convoluted social world is really what shaped our hefty, intricate brain and that those other intellectual abilities arose largely as by-products of the capacity to organize complexity and to create internal models that could help predict the behavior of others as well as the future consequences of our own actions.

Not that long ago, mainstream clinical neuropsychology itself was focused almost entirely on general intellectual ability, memory, problem-solving, executive function, and the like, while emotion and social interaction were in charge of other specialties. Many considered improving cognition the *sine qua non* of neuropsychological rehabilitation (Robertson, 2001). Concurrent with the growing consensus that cognitive and affective functioning are less dichotomous than believed previously (see Damasio, 1994, for example), a more holistic view of brain function has emerged coupled with the acknowledgment that the brain is the driving force for many more functions than just intellect, and neuropsychology has expanded its purview accordingly. There is also increased recognition of the value of quality of life and interpersonal experience to recovery, and that social relationships, directly and indirectly, are often strong predictors of outcome after brain injury (Cattran et al., 2011; Fantie and Kolb, 1991; Morton and Wehman, 1995).

In light of the connectedness of cognition, emotion, and psychosocial functioning, all should be the focus of rehabilitative efforts. Therefore, neuropsychological rehabilitation can be defined as the set of applied practices that involve "the systematic use of instruction and structured experience" (Robertson, 2001) concerned with the "amelioration of cognitive, emotional, psychosocial and behavioural deficits caused by an insult to the brain" (Wilson, 2011) that are guided by neuropsychological theory and neuropsychological assessment.

Brief History

Although neuropsychological rehabilitation has emerged as a formal entity only relatively recently, the study of the injured brain and its recovery has a long pedigree shared by medicine, anatomy, neurology, neuroscience, and neuropsychology. Space limitations preclude a comprehensive review of this history. Nevertheless, there are several excellent books on this topic that should more than whet the appetite of the interested reader (Corsi, 1991; Finger, 1994, 2000; Marshall and Magoun, 1998). What follows is a brief sample of some of the brain science pioneers who have made contributions especially relevant to neuropsychological rehabilitation. This list is incomplete, by necessity, and is not meant to be an exhaustive *dramatis personae*.

Paul Broca

Nineteenth-century French neurologist, Paul Broca (1824–80), known best for his discoveries related to the neurological basis of speech and language (Broca, 1861, 1863, 1866; Ryalls and Lecours, 1996), recommended that if one wished to teach an aphasic patient to speak again, one should approach the task with the "perseverance" and "indefatigable consistency of a mother who is teaching her infant to speak" (Broca, 1865: p. 390).

> Puis, comment sait-on que l'aphémique n'est pas capable d'apprendre à parler avec l'hémisphère droit qui lui reste? A-t-on essayé de faire son éducation? lui a-t-on donné ces leçons de tous les jours, de toutes les heures, de tous les instants à l'aide desquelles on finit à la longue par faire parler un enfant? Pour ma part, je suis convaincu que, sans rendre aux aphémiques la partie de leur intelligence qui a péri avec une partie de leur cerveau, on pourrait, en y mettant assez de persévérance, en les traitant avec l'infatigable constance de la mère qui apprend à parler à son enfant, on pourrait, dis-je, obtenir des résultats considérables.

Broca based this advice on his conclusion that, without the return of the part of their brain that had been lost, aphasics might best be taught to speak as though they were learning to do so for the first time because the processes involved when infants learn are different from those of an adult.

Shepherd Ivory Franz

New Jersey-born neuropsychologist Shepherd Ivory Franz, author of *Nervous and Mental Re-Education* (1923), investigated how well clients with aphasia benefitted from therapy. Franz, like Broca, also observed that the process of recovering from aphasia resembled learning a new skill more than merely reacquiring a habit established previously (Franz, 1905). Consequently, many subsequent rehabilitative treatment techniques designed for those with brain damage put an emphasis on learning new skills (Brewer-Mixon and Cullum, 2013; Witsken et al., 2008).

Franz made significant contributions to the science of rehabilitation in the laboratory as well as the clinic (Colotla and Bach-Y-Rita, 2002). He, along with Robert Ogden, also showed that forcing a monkey to use its affected arm after motor cortex ablation produced significant recovery of function that was not obtained in animals with similar lesions that were not forced to use the affected limb (Ogden and Franz, 1917), which had implications for people with hemiplegia, in particular, as well as other similar disabilities resulting from neural injury.

Otfrid Foerster

The German neurologist and neurosurgeon Otfrid Foerster (1873–1941), who had Vladimir Ilyich Lenin as a patient (Sarikcioglu, 2007), was a major influence on neurology and the emerging field of neurosurgery (Loring, 2010). His contributions to neuropsychological rehabilitation included a better understanding of the structure of the nervous system in general and the neuroanatomical substrata serving functional processes. This knowledge benefitted the design of more effective therapies and treatments.

Foerster (1930) conceptualized two fundamental processes as the bases of functional recovery after neurological insult. These are (1) regeneration and (2) reorganization. Regeneration involves the regrowth or replacement of the injured brain or nerve tissues so that any function that is restored is the result of a direct replacement of the damaged circuitry. During reorganization, on the other hand, it is the undamaged neural structure that alters its structure or actions to restore the original function subserved by the lost tissue. Therefore, surgery and prolonged exercise can both promote recovery of function by different means, each effecting one of the processes of regeneration and reorganization, respectively (Benton and Tranel, 2000).

More than any other branch of psychology, neuropsychology has been involved with the "cruel experiments of nature," a phrase used by G. Stanley Hall in his preface to Freud's *A General Introduction to Psychoanalysis* (1920). It is not surprising, then, that two World Wars would result in a surge in new knowledge about recovery from traumatic brain injury.

Walther Poppelreuter

At the beginning of World War I, Walther Poppelreuter (1886–1939), a German psychologist and neurologist, was stationed at the Psychiatric Hospital of Cologne, where he specialized in working with soldiers who had suffered head injuries. This work continued after the War at the Institute for Applied Psychology in Bonn and eventually the University of Bonn (Boake, 2003). Poppelreuter is associated with the following: (1) the notion that one should concentrate on the mastery of accuracy first and speed second when trying to teach a skill requiring both, known as Poppelreuter's law (but see Hellebrandt (1972)), and (2) the introduction of the Overlapping Figures test (Della Sala et al., 1995; Lezak et al., 2004: p. 403).

Kurt Goldstein

A contemporary and compatriot of Poppelreuter during World War I, Kurt Goldstein (1878–1965) also treated German soldiers with war-ravaged brains. Notably, both Goldstein and Poppelreuter developed and promoted the use of quantitative neuropsychological assessment methods to isolate and delineate deficits, to identify brain lesion–behavioral dysfunction relationships, and to inform treatment (Sullivan and Tapert, 2013). In addition to developing procedures for treating impaired reading, writing, and speech, which guided subsequent rehabilitative efforts, Goldstein also devised new methods that could be used to help shape specific target behaviors during recovery (Brewer-Mixon and Cullum, 2013; Witsken et al., 2008).

Goldstein developed a theoretical model for neuropsychological rehabilitation that, on the surface, appears similar to that of Foerster (see earlier entry), comprising two major mechanisms of recovery, one direct and one indirect, but their theories differ at their philosophical core. Addressing the scientific 'facts' associated with a brain injury (Prigatano, 2013), Goldstein thought that repetitive stimulation might be able to restore a cognitive function that had been disrupted by injury only if a sufficient portion of the related neuroanatomy was still intact. In the case of the complete loss of the relevant tissue, rehabilitative efforts would be best directed toward recuperation (Robertson, 2001). As a neurologist and *psychiatrist*, as opposed to a neurosurgeon such as Foerster,

Goldstein focused his theory less on the specific neuroanatomy involved in the injury and more on the phenomenological effects that trauma imposed on the injured person as an entire organism striving to function within an environment (Goldstein, 1939, 1963). For example, Goldstein (1942) emphasized how functional deficits could thwart an individual's resumption of a purposeful everyday life. According to Goldstein, brain injury changes the entire person, forever, and this experiential 'fact' produces what Goldstein referred to as a 'catastrophic reaction,' which has widespread effects and poses the major obstacle to social adjustment (Prigatano, 2013; Sullivan and Tapert, 2013). According to Prigatano (2000: p. 116), the first principle of neuropsychological rehabilitation is that the "clinician must begin with patient's subjective or phenomenological experience to reduce their frustrations and confusion in order to engage them in the rehabilitation process," and Goldstein also developed perceptive methods to help patients cope with these issues (Prigatano, 2013).

Alexander Romanovich Luria

World War II also produced an abundance of opportunities for gaining new knowledge about the sequelæ of brain trauma. Most notable, perhaps, was the work of A.R. Luria (1902–77), a psychologist and physician, who treated wounded Russian soldiers. He was the author of *The Man with a Shattered World: The History of a Brain Wound* (1972), arguably the best case study written about a person's recovery from a devastating brain injury. Luria had a profound influence on the development of neuropsychology as a result of a career treating patients with dysfunctions that ranged from the simplest to most complex neuropsychological functions (Brewer-Mixon and Cullum, 2013; Christensen and Caetano, 1996). In particular, his creative (and often improvised) assessment techniques provided a functional dissection of the precise nature and component features of the neurocognitive deficits of concern. Luria's approach provided insight into understanding both the consequences of the injury and the normal functioning of the intact human brain (Luria, 1966, 1973). This analysis and identification of the basis of the manifesting deficit was at the heart of what Luria thought were the primary goals of neuropsychological rehabilitation, namely, that recovery could be maximized if therapies were custom-designed to the individual and targeted the specific problem either to restore the disrupted root function or, if that was not possible, to at least mitigate the adverse effects of the loss of that basic capacity (Christensen, 1989; Luria, 1963; Prigatano, 2013). Robertson (2001) listed Luria's four main principles of rehabilitation, which are as follows: (1) recognition that each person's brain and functional neural circuitry are unique, (2) employing the function of undamaged neural systems to substitute for those that have been compromised, (3) using speech or other aids to assist the conscious performance of behaviors that were automatic before the injury until those behaviors are again internalized and spontaneous, and (4) providing consistent feedback to patients, so they can monitor their progress (Luria, 1963).

William Ritchie Russell, Freda Gladys Newcombe, and William Alwyn Lishman

Work with wounded World War II veterans in Great Britain supported the creation of three seminal works in neuropsychology and neuropsychiatry: *The Traumatic Amnesias* (1971) by W. Ritchie Russell (1903–80); *Missile Wounds of the Brain: A Study of Psychological Deficits* (1969) by Freda Newcombe (1925–2001); and *Organic Psychiatry: The Psychological Consequences of Cerebral Disorder* (1978) by Alwyn Lishman (1931–present). In light of the relatively recent increased interest concerning the importance of rehabilitating noncognitive functions in a holistic therapeutic approach, these works were prescient. As Newcombe (1969) observed, "Few of the subjects complained of loss of intellectual efficiency when asked to describe in detail any symptoms or difficulties" and "There were more complaints of affective symptoms: a tendency to irritability, depression, or loss of confidence " (p. 53 cited in Prigatano (2013): p. 752).

Oliver Zangwill

In contrast to the respective models presented by Foerster and Goldstein, British neuropsychologist Oliver Zangwill (1913–87) described three cardinal processes of rehabilitation following brain injury: (1) *compensation*, which is "a reorganization of psychological function so as to minimize or circumvent a particular disability" (p. 63); (2) *substitution*, defined as "the building up of a new method of response to replace one damaged irreparably by a cerebral lesion." (p. 64); and (3) *direct training*, which is the restoration of the affected abilities through conscious practice in cases where the neural substrate has not been destroyed completely (Zangwill, 1947).

Issues and Recent Advances

After consulting a number of leaders in the field, Barbara Wilson (2011) described what she considered were 10 of the most important developments in neuropsychological rehabilitation over the previous 5 years. Her list follows, and these topics will serve as a guide for a brief review of what neuropsychological rehabilitation has been and what it is becoming.

Recognition of the Need to Evaluate Rehabilitation in More Appropriate Ways

Recognition of the need to integrate practical clinical experience with evidence-based measures and techniques is, in itself, a significant advance. Recognizing that the standard single- and double-blind randomized control trials with placebos are not always the best research designs in rehabilitation, or even appropriate, is leading to the development of new paradigms promising to strengthen future therapeutic efforts, for example, the development of single-case experimental design (SCED) (Perdices and Tate, 2009; Tate et al., 2008). In 2014, the journal *Neuropsychological Rehabilitation* published a special issue devoted to SCED (Evans et al.,

2014). This issue contained articles covering topics that included Bayesian analysis of data from single-case designs (Rindskopf, 2014), randomization tests of effect size (Heyvaert and Onghena, 2014), measuring procedural fidelity (Ledford and Gast, 2014), and using multilevel analysis to integrate results within and across SCED studies (Baek et al., 2014), among others.

Errorless Learning for People with Language Disorders

The goal of errorless learning (EL) is to reduce the number of mistakes made during the acquisition of new skills or facts as much as possible so that erroneous responses are not reinforced unconsciously or unintentionally, presumably by processes related to implicit memory. Wilson, Baddeley, and others (e.g., Baddeley and Wilson, 1994; Evans et al., 2000; Wilson et al., 1994) have found EL especially effective in treating people with severe memory problems in contrast to trial-and-error learning, and EL appears about as effective as errorful learning with language disorders, although EL is greatly preferred by the patients, who find it less frustrating (Raymer et al., 2010).

Theories and Models Influencing Rehabilitation

A single model is inadequate to accommodate the complexity and multidimensional nature of neuropsychological rehabilitation. "For assessment, we need to refer to theories and models of cognitive functioning, localization, ecological validity and others; for treatment, we need to refer to theories and models of learning, cognition, emotion, social functioning and many others; we also need to know about recovery, plasticity, social systems and other aspects" (Wilson, 2011: p. 37). Developments and improvements in the models and theories from many relevant fields have enriched neuropsychological rehabilitation and continue to inform rehabilitative theories, goals, and techniques.

Theory-Driven Rehabilitation Interventions for Executive Dysfunctions

Problems with executive functions are common after brain injury. Wilson (2011) reported that "some new and effective treatment strategies" have emerged based on Duncan's theoretical model that describes disordered executive function as "a defect … in the role of purpose: control of action by its intended result" (Duncan, 1986: p. 271). Robertson (1996) based goal-management training on this model, which has served as the basis of some promising results (e.g., Krasny-Pacini et al., 2014; Levine et al., 2000; Miotto et al., 2009).

Restitution of Working Memory Deficits

Working memory is a fundamental component of executive functioning. There have been multiple reports, from different groups, working with a variety of populations that have reported improvements in working memory through training, which generalize to other tasks and everyday situations (e.g., Serino et al., 2007 and Westerberg et al., 2007 in adults after traumatic brain injury (TBI) and stroke, respectively).

The Perception of Emotion and Its Rehabilitation

Survivors of TBI frequently experience changes in their ability to perceive and express emotion (e.g., Biszak and Babbage, 2014; Bornhofen and McDonald, 2007, 2008; Fantie et al., 2001). The processes related to the perception of emotional stimuli, such as facial expression, affective prosody, body posture, and other aspects of interpersonal and social communication, have finally achieved deserved attention after being neglected for decades by the majority of the mainstream scientific community, including behavioral psychologists, largely due to the constraints of behaviorism. Given how important this aspect of behavior is to functioning successfully in our daily lives in a social world in addition to the quality of life, this recognition is long overdue and will drive sorely needed developments in the remediation of deficits within this domain.

Brain–Computer Interaction

Faster computers, able to monitor brain-related activity recorded through techniques such as EEG, fMRI, or PET in real time, continue to support the development of a better understanding of how the brain works and the effects of brain damage as well as new tools to assist with diagnosis and rehabilitation. Wilson (2011) singled out two advances in the use of brain–computer interaction (BCI) related to neurofeedback: In the first, BCI controlled devices such as prosthetic limbs and wheelchairs (e.g., Tan et al., 2014) and in the second, BCI served as means to communicate with people who appear to be in a vegetative state, but who show good evidence of active cognitive function when their brain activity is monitored during certain situations. For example, these patients were able to modulate their brain activity differentially to provide meaningful yes–no responses to questions (e.g., Monti et al., 2010; Owen et al., 2006).

Virtual Reality

Neuropsychologists have been using computers to administer tests during neuropsychological assessments for about three decades, with benefits over paper-and-pencil measures that include improved procedural consistency across assessments as well as the ability to record response-related reaction times and to control the duration of stimulus presentations more precisely and accurately. Another promising and exciting recent application of computers involves the use of virtual reality (VR), which is producing novel and inventive procedures that benefit both assessment and therapy (Weiss and Klinger, 2009). As discussed earlier, executive functions are of particular importance to the ability to function in everyday life but are often compromised by brain injury. Assessing executive functions with traditional paper-and-pencil tasks is not completely satisfactory (Chan et al., 2008). VR can create more realistic and ecological valid simulations of the complex, sequential, multistage, and often simultaneous behaviors that are frequently compromised after brain trauma. For example, Raspelli and colleagues (Raspelli et al., 2010, 2009, 2012, 2011) developed a VR version of the Multiple Errands Task (Shallice and Burgess, 1991) that simulates a supermarket. Similarly, larger VR environments (e.g., a shopping mall, small neighborhoods) are being developed that can be used to assess

and train navigation, wayfinding, and spatial orientation abilities after brain damage (Carelli et al., 2009a,b; Koenig et al., 2009).

Cognitive Enhancement: Crosswords, Computers, and Video Games

Amy Jak et al. (2013) reviewed and evaluated outcomes from a sample of 21 cognitive training programs that used electronic activities and that included participants with traumatic brain injury, brain tumor, stroke, severe mental illness, as well as healthy individuals. Although these programs typically produced improvements on the training tasks themselves, there was not often evidence of lasting generalizability to other tasks or everyday activities. The computerized cognitive training did, however, appear to have a positive effect on the participants' perception of their social connectivity and self-efficacy. Jak and colleagues expressed concern about the poor methodology they found employed by many of the studies that they evaluated and remained optimistic about the potential for these activities to be used more effectively in the future.

Identity Issues following Acquired Brain Injury

There are issues related to a person's concepts of self and identity that must be resolved before brain trauma survivors can achieve their optimal potential (Ben-Yishay and Daniels-Zide, 2000; Prigatano, 1999). These concepts are central to the holistic approach to rehabilitation, albeit, they have not been defined well operationally (Wilson, 2011). The journal *Neuropsychological Rehabilitation* published a special issue dedicated to "The self and identity in rehabilitation" (Gracey and Ownsworth, 2008). This issue contained reports that show some promising work toward the resolution of this shortcoming by providing models that can help us think about the interactions of personal and social identity, cognition, and neural processes (e.g., Cloute et al., 2008; Haslam et al., 2008; Wilson et al., 2008; Yeates et al., 2008).

Support in the Early Stages of Dementia

Wilson (2011) noted the need for psychosocial (i.e., 'non-pharmacological') interventions to support those affected by early-stage dementia because of the relevant scarcity and limited efficacy of available medications as well as the need for outcome measures that do a better job of assessing the everyday, real-world benefits that interventions purportedly provide. A contemporaneous study by Clare et al. (2010) reported improved goal performance and satisfaction ratings in a group of people with early-stage Alzheimer's disease as the result of goal-oriented cognitive rehabilitation, suggesting the usefulness and value of this intervention to those with early-stage dementia and their families.

Computational Modeling

Within cognitive neuropsychology, a computational model uses sets of mathematical formulae to represent and simulate the processes underlying linguistic and cognitive abilities. These formulae are derived from a target theory and form the basis for a computer program that not only can perform the cognitive task of interest, but does so, presumably, in exactly the same way as a human would, at the functional, information-processing level (Caramazza and Coltheart, 2006). Computational modeling has done quite well replicating and predicting language and cognitive deficits, but has been less successful predicting recovery and rehabilitation in response to interventions (see Dell and Caramazza, 2008). There is a growing interest in trying to solve this problem (e.g., Welbourne and Ralph, 2005). Nevertheless, Wilson (2011) reports a personal communication from Matthew Lambon Ralph in which he noted, "the model does not get depressed after its stroke, it does not have a grieving family, it does not have to worry about the mortgage, and does not have to contend with other real-life issues" (p. 34). This observation underlines the need to adopt a big picture view when dealing with clinical populations and the challenge of rehabilitating a human being back to as normal a life as is possible.

The Holistic Approach to Rehabilitation

Perhaps the most significant development in neuropsychological rehabilitation over the past decade or so has been the increased acceptance of the holistic approach, the conceptual basis of which was Kurt Goldstein's 'organismic' theory of human nature (Goldstein, 1939, 1963). Put simply, in contrast to the notion that brain injuries produce cognitive or behavioral deficits that can be treated by focusing on that specific dysfunction within its domain, the holistic approach sees "the failure to function normally after a brain injury as the consequence of a combination of (or the interactions among) biological and behavioral causes" (Ben-Yishay and Diller, 2008: p. 79). The biological causes relate to the actual physical injury and the consequences of the damaged neural circuitry. These 'behavioral' causes, however, go well beyond the specific deficits manifested by damaged tissue and can include the full gamut of conscious and unconscious emotional, intellectual, and experiential responses to changes that have taken place in that person as an individual, as an emotional and social being, and as an organism interacting with its environment (see Ben-Yishay and Diller (1983) and Prigatano et al. (1986) for more comprehensive reviews). Thus, to maximize a person's adjustment to a brain injury, holistic approaches to neuropsychological rehabilitation require psychotherapy in addition to interventions directed at ameliorating cognitive and behavioral difficulties (Prigatano, 1999).

Future Directions

Barbara Wilson (2011) suggested the possible future developments in neuropsychological rehabilitation, which include the following: establishing stronger links with basic neuroscience, better use of imaging procedures, more and better collaboration with pharmaceutical companies, better evaluation of rehabilitation programs, and the need to educate researchers and practitioners as to the meaning and value of rehabilitation.

Prigatano (2013: p. 756, Table 2) presented the following as opportunities for advancing the field of neuropsychological rehabilitation:

1. The clinical utility as well as size effects of cognitive rehabilitation need to be thoroughly documented.

2. More time-efficient and 'user-friendly' memory compensation techniques need to be developed.
3. The characteristics of the psychotherapist and of the patient that lead to effective symptom reduction and ultimate maintenance of employment following severe traumatic brain injury need to be thoroughly described.
4. The characteristics of the therapist and the patient that allow for the development of the therapeutic or working alliance need to be thoroughly studied.
5. Long-term cost–benefit analysis of neuropsychologically oriented rehabilitation needs to be conducted.
6. Techniques for improving family education and involvement in the rehabilitation process of children and adults need to be developed.
7. The neuroimaging correlates (structural and functional) for improved cognitive and behavioral functioning in adults and children following severe traumatic brain injury need to be better understood.
8. The role of deep brain stimulation and the recovery of certain cognitive functions (for example, memory) after severe post-acute traumatic brain injury should be explored.
9. Clarification of what are the 'direct' versus 'indirect' effects of brain injury needs to be specified and studied in both clinical and experimental research.
10. Barriers for conducting effective neuropsychological you militate in of children need to be eliminated.

Abstract

The development of the human brain is a prolonged process that begins 3 weeks postconception and continues well into adulthood. The phases of brain development are outlined and discussed in relation to the prenatal and postnatal periods of life. The features of brain construction that promote neural plasticity are discussed in the context of the interaction of our inherited genes (nature) and our environmental experiences (nurture).

Introduction

Human brain development is a protracted process that begins shortly after conception and continues at least into the third decade of life. The brain is crafted by the lifelong interplay of generative (cell birth and synapse formation) and degenerative processes (cell death and synaptic pruning), which are modulated to varying degrees by an individual's experience. The process of brain development is intricately programmed by information carried on DNA. Although the process is fundamentally the same for each individual, environmental exposures can alter the manner in which the program becomes manifest. This environmental modulation of genetic expression is called epigenetic programming and its effects can be seen in the preconception period (e.g., Mychasiuk et al., 2013), the prenatal period, (e.g., Mychasiuk et al., 2012) and through the life span of the individual (e.g., Harker et al., 2013). Mounting evidence demonstrates that experiences of our forebears can and often do result in epigenetic changes in gene expression ultimately changing the expression of proteins. Because proteins are the building blocks of the brain, different proteins build different brains by modifying cell number, cell connectivity, brain size, and ultimately, behavior. Epigenetic programming thus provides an adaptive means for an organism to prepare its brain for the unique environmental challenges that it will face without changing its genetic blueprint.

Phases of Brain Development

The process of brain construction occurs in seven well-defined phases that extend over a prolonged period of brain development (Kolb and Whishaw, 2014). Some phases are more or less confined to restricted periods, whereas other phases are in play for extended periods of time. The seven phases of brain development are

1. cell birth (neurons, glia, microglia precursors),
2. cell migration,
3. cell differentiation,
4. cell maturation,
5. synaptogenesis,
6. cell death and synaptic pruning, and
7. myelination.

Each phase will be considered in depth in the developmental epoch(s) during which it predominately occurs.

Formation of the Brain: Embryonic Development (Conception to Week 8)

By embryonic day 13 (E13), the primitive node and the primitive streak appear during the process known as gastrulation, whereby the single-layer blastula is replaced by a trilayer structure. At the end of gastrulation (E20), the endodermal,

mesodermal, and ectodermal layers of the trilamina have formed. The ectodermal layer gives rise to both the skin and the central nervous system (CNS). The neuroepithelial cells (NECs), which eventually produce cells that make the neurons and glial that form the brain, are found within this layer. The neural plate forms on E21, and by E22 the neural groove becomes apparent. The neural groove fuses starting on E23 to form the neural tube (neurulation) with the central section closing first. The rostral portion of the neural tube is inhabited by the earliest migrating cells and becomes the brain, while the caudal portion receives later migrating cells and forms the spinal cord (Stiles and Jernigan, 2010). The rostral and caudal regions of the neural tube are the last to close. Neural tube defects are birth defects that affect the brain or spinal cord. Failure of the rostral section of the neural tube to close on E23–E26 results in a condition known as anencephaly, where the brain and skull fail to fully develop. Infants born with anencephaly usually lack sensory processing abilities and are unable to feel pain. They generally die shortly after birth. Spina bifida is the result of incomplete closure of some portion of the caudal end of the neural tube on about E28. The symptoms of spina bifida range in severity, but it is most commonly characterized by paralysis of the legs. Both anencephaly and spina bifida commonly result from a lack of the B vitamin, folate, in the diet. The cylindrical cavity in the neural tube eventually becomes the ventricular system and the NECs inhabit this region, also known as the ventricular zone (VZ) (*Phase 1-cell birth*). The NECs are aligned in the ventricular zone in an apicobasal fashion. At the ventricular (apical) surface, the NECs are bound together by both *tight* and *adherens junctions* and at the pial (basal) surface by *integrins*. During neurulation, the neural stem cell population undergoes rapid expansion by symmetric cell division of the NECs. A primitive map that provides a basic blueprint for brain organization emerges at this stage of development. In order to supply the demand for neurons to populate the brain, on E25 the NECs divide in a symmetrical fashion. Symmetrical cell division produces two NECs with each division and this process continues until E42. By E28, the rudimentary structures of the forebrain (prosencephalon), midbrain (mesencephalon), and hindbrain (rhombencephalon) are visible in the human embryo (Stiles and Jernigan, 2010). Just prior to neurogenesis, NECs begin to transform into radial glial cells (RGCs). Recent work on neural progenitors has led to an understanding that diverse populations of progenitors exist. Three new subclasses: the intermediate progenitor cell (IPC), the short neural precursor (SNP) with an apical attachment at the VZ but no basal attachment at the pial surface, and basal radial glial cells (bRGCs) with basal attachments at the pial surface but no apical attachment in the VZ, have been described (Franco and Muller, 2013). Traditionally, RGCs were thought to divide asymmetrically to self-renew and provide a non-RGC daughter cell (E42–E108). It turns out that some but not all of the daughter cells are postmitotic neurons. Most of these daughter cells are IPCs. IPCs undergo symmetrical divisions to self-renew but most supply pairs of neurons. The IPCs occupy a basal position in the ventricular zone and ultimately form the proliferative region known as the subventricular zone. SNPs are similar in function to the IPCs in that they produce neurons but they differ in that they maintain an apical ventricular attachment and remain in the VZ. The bRGCs that occupy the outermost region of the SVZ self-renew and generate IPCs and neurons. At the end of neurogenesis, (E108; Clancy et al., 2001) both RGCs and bRGCs transform into progenitors that produce astrocytes (**Figure 1**).

Figure 1 After Paridaen and Huttner, 2014.

Formation of the Brain: Fetal Development (Week 9 to Birth)

During this phase of brain development, the previously smooth brain acquires the folding pattern with gyri (bumps) and sulci (grooves) typically seen in the mature brain. After cells are born in the VZ or SVZ, they migrate away in a radial fashion with the cells that form the deepest layers of the cerebral cortex leaving first (*Phase 2-cell migration*). As cells continue to form, the layers gradually build with the newest arrivals seated atop those most recently placed in a so-called 'inside out' fashion. A notable exception to the inside out rule is the first wave of cells that leave the proliferative zone. These cells form a primordial structure known as the preplate (Bayer and Altman, 1991). Once formed, the preplate is split into two by the next wave of arriving cells producing a transient subplate and marginal zone (layer 1). The new region that these cells form is known as the cortical plate, and the first cells to populate the cortical plate are the cells destined to become layer 6 cells. The marginal zone contains a population of cells called Cajal–Retzius (CR) cells. These cells provide important signaling information for newly arriving neurons to position them in their correct layer in the cortex. The CR cells produce a substance called *reelin* that signals migrating neurons to stop their journey and take a position in the developing cerebral cortex. Animals with reelin deficiencies fail to develop laminar structure in the cerebral cortex. In humans, abnormalities in the reelin signaling cascade are implicated in a variety of neurodevelopmental disorders including schizophrenia, autism, major depression, and bipolar disorder (Folsom and Fatemi, 2013). RGCs that are anchored at the ventricular zone and the pial surface form the guideposts for the migrating cells. Newly born neurons climb along the radial glia fibers to reach their destination, and until recently, it was thought that all of the neurons that climb an RCG are progeny of that cell. Recent experimental evidence has cast doubt on this view. Because different cell types inhabit the different cortical layers, it has been surmised that the cortical progenitors have the ability to produce a broad class of neural cell types (*Phase 3-cell differentiation*). IPCs produce neurons whereas, RGCs give rise to both projection neurons and astrocytes (Franco and Muller, 2013). As successive layers of the cortical mantle are formed, the progenitors become more limited in the cell types that they are able to construct. This process is known as fate restriction and it is thought to account for how progenitors are able to manufacture the variety of cells required to build the brain. In a recent paper, Franco et al. (2012) describe work done in a murine model that demonstrates that birthdate alone does not account for the ultimate position of neurons in particular cortical layers. Rather, they have identified RGCs sublineages that are responsible for producing either the lower (V and VI) or upper (II, III, and IV) cortical lamina. IPCs and some RGCs appear to bear the same transcription factor (Cux2 and are thus Cux2+) as neurons destined for the upper cortical layers. RGCs that lack expression of Cux2 (Cux2−) generate neurons destined for lower cortical layers. Results of this work suggest that birthdate may not be the cause for layer specification of the cerebral cortex. It appears that IPCs and RGCs that produce upper-layer cortical neurons just happen to do so at a later time than the RGCs that generate the lower-layer neurons. This work suggests that cell fate specification drives birth order and not the reverse as was previously believed. Cux2− RGCs stop symmetrical divisions and start to produce neurons before Cux2+ cells, allowing expansion of the Cux2+ progenitor pool. The authors of this work note that upper cortical layers are expanded in primates and are necessary for sophisticated associative connectivity. They propose that defects in the generation of these cells could result in conditions such as autism and schizophrenia. Most radially migrating cells are glutamatergic (use glutamate as their principal neurotransmitter) and comprise approximately 80% of cortical neurons.

Inhibitory cortical interneurons (ICIs) arise from different origins. Three ganglionic eminences, the medial, lateral, and caudal are confirmed sources of ICIs, whereas the rostral migratory stream, the septal region, and the anterior region of the cortical plate may be additional generative sites (Wonders and Anderson, 2006; Al-Jaberi et al., 2013) ICIs have multiple phenotypes based on their morphology, neurochemical constituents, and physiology. A uniting feature of ICIs is their use of the inhibitory γ-aminobutyric acid (GABA) as their neurotransmitter. Postmitotic ICIs migrate in what is called a tangential fashion and rely on a number of molecular guides or tropic factors to reach their destination. The guidance molecules arise from local regions of the cortex and help the interneurons reach their final destination (Stiles and Jernigan, 2010). Proper functioning of the cerebral cortex depends on ICIs (20% of cortical neurons). In addition to the key role that ICIs play in modulating cortical output, they are also involved in developmental processes including regulation of neuron proliferation, migration, and plasticity of cortical circuitry (Wonders and Anderson, 2006). A fascinating feature of the developing cortex is the depolarizing effects of GABA in the immature brain. Although this phenomenon has been recently called into question (Bregestovski and Bernard, 2012), overwhelming evidence seems to support the finding that in immature ICI's, GABA has an excitatory action by depolarizing membranes and sometimes even causing sodium (Na^+) mediated action potentials (Ben-Ari et al., 2012). Excessive accumulation of the chloride ion (Cl^-) in immature neurons may mediate the excitatory action of GABA, and indeed the shift in GABA polarity is concurrent with a progressive reduction of intracellular Cl^-. It appears that this inverted excitatory action of GABA during development may have an organizational role in cell birth, migration (especially the tangentially migrating ICIs), synaptogenesis, and network formation. Tyzio et al. (2006) describe the influence of oxytocin during delivery as the cellular switch that changes the polarity of GABA function to inhibition. Failure to assume the fully mature GABA system is associated with the appearance of epileptic seizures (Aronica et al., 2011).

Once neurons reach their final destination, they extend dendrites and an axon (*Phase 4-cell maturation*) in an attempt to make connections with other cells and become an integral part of a communication network. Dendrites gather information from other neurons and the axon provides a mean of sending information to neurons further down the communication line. Many dendrites extend from a neuron to receive input from cells in the information network, but a single axon conveys

information processed by the cell. In order to make appropriate contacts, the axon has a growth cone on its leading edge. The growth cone is guided by sampling locally produced tropic molecules that ultimately assist the axon in finding its intended target. Once that target is identified, a connection called a synapse is formed (*Phase 5-synaptogenesis*). The synapse provides the means for cell-to-cell communication. In the context of the synapse, the axon is considered the presynaptic terminal and the dendrite, the postsynaptic terminal.

Interestingly, the formation of the brain also depends on degenerative processes that commence in the prenatal period of life. Programmed cell death or apoptosis (*Phase 6-cell death and synaptic pruning*) is instigated to reduce the number of cells in the brain that have failed to make useful connections or have connections that are underutilized (Chan et al., 2002). During this process, a cascade of death promoting genes are expressed that initiate a suicide program in the cell (for more details, see Section Formation of the Brain: Postnatal Development). Cells that have established stable and vibrant connections are protected from apoptosis by neurotrophic factors supplied by other cells in the circuit.

Formation of the Brain: Postnatal Development

The process of neurogenesis (*Phase 1-cell birth*) persists through the postnatal period in a restricted manner. Cells continue to form in the SVZ, which are destined to populate the olfactory bulb and they then migrate (*Phase 2-cell migration*) via the rostral migratory stream (RMS) to their target site. Postnatal neurons are also born in the dentate granule layer in the hippocampus. Neural proliferation in these two privileged areas continues throughout the life span. Proliferation and migration of cells destined to become glial cells begins in the prenatal period and continues for an extended time in the postnatal period. Glial progenitors multiply in the SVZ and then migrate out to the white matter eventually reaching the cortex, striatum, and hippocampus. The mode of emigration for glial progenitors is dependent on their ultimate destination. Cells destined for dorsal areas migrate in a radial fashion to the overlying corpus callosum, where they remain or continue on along RGCs to their target in cerebral cortex. Cells destined for lateral cortex follow white matter laterally and then exit to follow RGCs to their terminal location. Some glial progenitors track along the corpus callosum to reach the opposite hemisphere and others follow blood vessels to their target (Cayre et al., 2009). It appears that glial progenitors, particularly oligodendrocyte progenitor cells (OPCs) are retained in the cerebral cortex for an indefinite period of time. Even the adult brain has the ability to produce astroglia and oligodendroglia and both can arise from OPCs. Synaptogenesis (*Phase 5-synaptogenesis*) that began in the prenatal period continues in the postnatal period and throughout the life span of an individual. Dendrites on a single neuron can make tens of thousands of connections with other neurons and it appears that the number of connections varies with the cortical area. At the site of contact, the neuron usually elaborates a dendritic spine to enhance the effectiveness of the synaptic site. Fewer dendritic spines are observed in posterior regions (visual areas) than in anterior regions of the brain (frontal lobe) and in the most anterior areas (prefrontal cortex), estimates of 23 times more synapses than in primary visual cortex have been derived (Elston, 2003). Most dendritic spines are sites of excitatory neural transmission. Excitatory synapses, also known as Type I synapses, are morphologically distinct from inhibitory or Type II synapses (Gray, 1959). Type I synapses are characterized by round synaptic vesicles in the presynaptic terminal, a wide synaptic cleft or space between the presynaptic and postsynaptic membranes, a large active zone, and a dense network of proteins on the postsynaptic membrane known as the postsynaptic density. Inhibitory synapses are conversely identified by oval or flattened synaptic vesicles in the presynaptic terminal, a narrow synaptic cleft, a small active zone, and a sparse postsynaptic density (Kolb and Whishaw, 2014).

Apoptosis (*Phase 6-cell death and synaptic pruning*) continues to play a major role in brain development in the postnatal period. 'Use it or lose it' becomes the rationale for brain architecture at this juncture, and it does not just apply to dormant cells. The exuberant production of synapses is also subject to this philosophy. Underused synapses are removed in a process called synaptic pruning. Recently, the role of microglia in both apoptosis and synaptic pruning has been described (Paolicelli et al., 2011; Wake et al., 2012). Microglia are not derived through the same precursor cells as neurons and astroctyes, but rather originate from mesodermal myeloid progenitors that also produce macrophages and blood cells. Microglia immigrate to the CNS early in embryogenesis where they proliferate. During development, microglia typically display an ameboid appearance in contrast to the ramified phenotype that characterizes microglia in the adult CNS. Estimates are that approximately 50–70% of the cells born into the brain are removed through apoptosis (the number varying with the location within the CNS; Stiles and Jernigan, 2010; Rabinowcicz et al., 1996), and approximately 40–50% of synaptic connections are lost through synaptic pruning (Low and Cheng, 2006). Cell loss and synaptic pruning provides a means for tuning brain connections by ramping up those that are important and eliminating those that are not.

Although myelination (*Phase 7-myelination*) proceeds to a limited extent in the prenatal period, it ramps up after birth and continues well into the third decade of life. The process of myelination frequently heralds the maturation of cortical areas. Primary motor and sensory areas of the brain myelinate first and association areas myelinate last. For example, the first cortical area to myelinate is motor cortex and myelination of the dorsolateral prefrontal cortex occurs last (Flechsig, 1901). OPCs upon reaching their final destination differentiate. Processes are extended and begin to form myelin that wraps around axons and acts as insulation to speed up the transmission of electrical signals. For myelination to occur, an ample supply of an energy substrate needs to be readily available. In the absence of a readily available energy source, myelination is impaired and OPC's risk enacting the apoptotic pathway. Although glucose is often that substrate under certain conditions of intense neural activity, lactate may provide another resource for the energy required. In cases of anoxia during myelination resulting in cerebral palsy or periventricular leukomalacia, lactate may be an important factor in minimizing

the devastating outcomes by supporting integrity of immature oligodendrocytes (Rinholm et al., 2011). It is clear that the role of oligodendroglia extends far beyond that of just insulating axonal fibers. In a recent paper (Morrison et al., 2013), the role of oligodendroglia in supporting axonal health and function was examined. It appears that axons are metabolically costly to maintain and once myelinated, have limited access to the extracellular fluid to fulfill their energy requirements. Oligodendroglia may provide an important link to energy supplies for neurons. Another recent study compared the time course of myelination in humans and chimpanzees, our closest living relatives (Miller et al., 2012). The authors in this study discovered that while chimpanzees completed the process of cortical myelination by the time of sexual maturity, in humans this process extended well beyond late adolescence. They conclude that extended timing of myelination in the human brain may be in part responsible for the greater degree of cognitive development and cortical plasticity observed in humans. They also propose that this extended period of maturation makes the human brain more vulnerable to psychiatric disorders that have typical onset in adolescence or early adulthood like schizophrenia.

Experience and Brain Development

The rudimentary plan for constructing the human brain is encoded in the genome, but much of the connectivity is unspecified and depends on the input of experience to complete the wiring. Processes that proceed without the need of external experiences have been described as experience independent (Shatz, 1992). Such developmental processes rely on internally generated activity to proceed rather than externally generated environmental input. An example of such a process is the formation of layers in the lateral geniculate nucleus based on firing patterns of retinal ganglion cells. Experience-expectant plasticity (Greenough et al., 1987) occurs when the brain uses information derived from the environment to drive the normal development of a structure. If the expected experience is unavailable, the structure will develop in an abnormal fashion or will fail to develop. The development of ocular dominance columns in visual cortex is achieved through experience-expectant plasticity. Experience also modifies the construction of the brain through a process termed experience-dependent plasticity (Greenough et al., 1987). In this form of plasticity, structures in the developing brain do not require particular experiences but may be modified or changed by environmental exposures. Learning is a form of experience-dependent plasticity. All seven phases of brain development can be altered to a certain extent by experience. Experience-dependent plasticity allows the developing brain to change responsively to experiential inputs and thus adapt to the unique environmental challenges an individual may face.

Summary

Brain development has a protracted time course in humans beginning in the third week postconception and extending to the third decade of life. The brain develops in seven well-defined phases that overlap and are repeated over the course of development. Neurodevelopmental disorders arise when processes engaged during construction of the brain go awry. Experiences of an individual play a fundamental role in producing a brain uniquely constructed to complement the environmental niche that individual occupies.

Abstract

The evolution of the human brain has been a largely mosaic affair, in which changes of reorganization of brain components, increases of brain size through both hyperplasia and hypertrophy, underlain by neurogenomic changes, have occurred sometimes independently, sometimes together. The direct evidence for these changes relies on paleoneurology based on endocast studies (where casts are made of the inside of the cranial cavity), which provide the best evidence for volume changes through time and occasionally some convolutional details of the once-pulsating cerebral cortex. Both comparative neuroscience and neurogenomics provide essential information of brain and behavioral variations, which allow more accurate interpretation of the endocasts, which are often poor in detail even though the extant species studied are not direct ancestors to humans. Reorganizational changes include a reduction of primary visual cortex and relative enlargement of posterior association cortex, expanded Broca's regions, as well as cerebral asymmetries. The size of the hominid brain increased from about 450 ml, 3.5 Ma, to our current average volume of 1350 ml. These two changes through time were sometimes gradual but not always.

The evolution of the human brain has largely been a matter of integrating both increases in the size of the brain, and the brain's organization through the past 3–4 My. Three lines of evidence are used by paleoneurologists to ascertain how these events might have occurred: (1) Direct evidence is from the brain endocasts of fossil hominids. (2) The indirect evidence is from comparative neuroscience, where variations in brain structures can be related to variations in behavior. The latter evidence is 'indirect' because extant living animals are not ancestral to humans. Indeed, the last common ancestor for apes and the hominid line existed some 5–7 Ma. (3) Newer neurogenomics evidence also promises to provide important clues to how and when certain aspects of brain changes occurred during human evolution.

The human brain evolved from an early hominid 3–4 Ma, *Australopithecus afarensis*, having a size of roughly 400 ml to our present average of 1330 ml. These brain size increases, at different taxonomic levels, were mostly allometric, that is, related to body size, but not always. Integrated with these changes in brain size was reorganization of the cerebral cortex, as well as subcortical structures such as the hippocampus, amygdala, and so forth, to mention a few important structures relating to aspects of social behavior that cannot be seen on endocasts.

At least three areas of the cerebral cortex were affected at different times: (1) a relative reduction of primary visual striate cortex (V1, PVC) and an attending relative increase in posterior parietal association cortex; (2) a change in Broca's region, resulting in a more human-like pattern; and, (3) increasing degrees of cortical asymmetry, as well as increases in overall brain size, and number of neurons.

When did the human brain evolve, and how did it happen? Obviously, to answer this question will require a time machine, and thousands of generations of observations to ascertain both the variability and direction of selection pressures in the past. We can, however, flesh out an initial understanding of how we got to be the animal *par excellence* that utilizes its brain for intelligent rationalizations based largely on the use of arbitrary symbol systems. The evidence consists of two components: (1) the 'direct' evidence from the fossil record; and (2) the 'indirect' evidence of the comparative neuroscientific record of extant living animals, particularly those most closely related to us, such as the chimpanzee and bonobo. There is a third possibility: since the human genome project has sequenced almost all of the genetic code, the future study of evolutionary neurogenomics might provide more data about the actual genetic history of our genus through time, as well as that of the great apes mentioned previously. As this latter possibility is simply a mote in our eye at present, this article must concentrate on the evidence provided by the first two components.

Lines of Evidence

Direct Evidence

The term *paleoneurology* is used to describe evidence appraising the size and morphology of the casts made from the inside of actual fossil cranial remains. Occasionally, the casts are 'natural,' that is, where fine sediments have filled the inside of the cranial cavity, and become compacted through time. These casts often retain whatever morphological details were imprinted on the internal table of bone of the cranium. The famous australopithecine Taung child's skull, described by Dart (1925), is one of the best-known examples. Curiously, these 'natural' endocasts are only found in the S. African australopithecines, of which several exist, dating from about 3.0 My to about 1.5 My. Most often, the paleoneurologist makes a cast of the inside of the fossil skull using rubber latex, or silicone rubber, and extracts this from the cranium. The partial cast is reconstructed by adding Plasticine (modeling clay) to the missing regions. The whole is then measured by immersion into water, and the amount of water displaced is regarded as the volume of the once-living brain. Other measurements and observations are made on the original cast. More recently, 'virtual' endocasts have been made from CT scans of intact or partial crania, which have the advantage of being noninvasive, and as the method is computer driven, there are different algorithms for measuring the size of the endocast and other metrics (Weber et al., 2012).

During life the brain is surrounded by three dural tissues (dura mater, arachnoid tissue and its cerebrospinal fluid, and pia mater) that interface between the actual brain tissue (cerebral cortex, mostly) and the internal table of bone of the skull. The gyri and sulci (convolutions) of the once-pulsating cerebral cortex are rarely imprinted on the interior of the skull, and the degree of replication often varies in different regions, for example, sometimes the frontal lobe imprints more details than the parietal lobe, and also by age. The degree of replication also varies in different animals. Two extremely important considerations emerge from this: (1) the resulting imprints are never complete and thus 'data poor,' and never include subcortical structures; and (2) controversial interpretations of what the underlying brain once looked like are guaranteed. Nevertheless, these endocranial casts do provide extremely important information regarding size, shape, rough estimates of the lobar dimensions of the brain, and cortical asymmetries that have relationships to hemispheric specializations, including handedness. In addition, if the imprints of the underlying gyri and sulci (i.e., the characteristic shapes of the brain) are available, these can provide important information regarding the organization of the cerebral cortex, and whether the patterns of these are the same or different as in known extant primate brains. The infamous 'lunate sulcus' is a good example, as it is a demarcation boundary between purely sensory primary visual striate cortex (PVC) and multimodal association cortex. When the lunate sulcus appears in an anterior position, it is most similar to the condition known in modern apes. When it is found in a posterior position, it is more in a human-like condition. Ascertaining its correct position is essential in deciding whether or not such a fossil hominid had a brain organized along human or ape lines. In modern humans, the 'lunate' is only partially homologous with that found in apes, and is usually fragmented (Allen et al., 2006). Finally, meningeal arteries and veins that nourished the dura mater also imprint on the internal table of bone, and these sometimes show patterns that are useful for deciding taxonomic issues; these have no known relationship to behavioral functions of the brain. (See also Grimaud-Hervé in Holloway et al., 2004; for further discussion and illustrations.)

Indirect Evidence

This line of evidence is 'data rich,' providing comparative neurological information on living species, such as brain size (both absolute and relative, i.e., related to body size), the actual makeup of the brain from the gross to microscopic levels, including neural nuclei, fiber systems and interconnections, and distribution of neurotransmitters and neuroreceptors. Additionally, the brain can be studied ontogenetically, and neuroscientists can actually study the relationships between how the brain varies neurologically and how these variations relate to the behavioral variation. Neurogenomic information will also add considerable details as to how living brains vary and operate, both within and between different species. This richness is simply lost to the paleoneurologist as it is not available as direct evidence. However, it is necessary to realize that the extant living species – for example, bonobo, chimpanzee, macaque – are end points of their own evolutionary lines of development and are not our ancestors, however closely related (*see* Primates, Evolution of). It is the blending and complementation of these two approaches that provides the best evidence for when and how our brains evolved.

Characteristics of the Human Brain

Brain Size, Absolute and Relative

The human animal is obviously obsessed with size, and those who study the brain comparatively, perhaps more so. With an average brain weight of 1330 g (Tobias, 1971), the human species has the largest absolute brain size within the primate order, but is actually dwarfed by elephants and some of the whales, where brain weight can exceed 7500 g. Of course, the body weights are very much higher in elephants and whales. But even for its body weight, *Homo sapiens* does not have the largest relative brain weight, being outdone by several monkeys, some rodents, and even some fish. Normal modern human brain size varies between roughly 900 and 2000 g, although some very small number of exceptions does occur, with sizes ranging from about 750–900 and 2000–2200 g. There is human population variation as well as differences between the sexes. In general, people who live in the Arctic have larger brains than those who live in the tropics; the small-statured Ituri forest pygmies in Africa appear to have some of the smallest brains in the world. Males in all populations for which good autopsy data have been gathered show brain sizes on the average of 100–150 g greater than females, an amount roughly the same as the range of modern human racial variation. It should be pointed out that these differences, and their possible relationship to cognitive skills, are highly controversial and simple correlations are deceptive (Holloway, 1996, 2008; Nyborg, 2003). Table 1 provides a listing of the major fossil hominid taxa and their respective brain sizes. Notice that the range of values from the earliest australopithecine to modern *Homo* is roughly 1000 ml, or about the same amount as the normal range of variation within our species.

Encephalization (Encephalization Coefficient, EQ)

Nevertheless, the human animal does come out on top of the evolutionary heap when its absolute brain and body weights are considered together. When the log (base 10) of brain weight is plotted against the log10 of body weight for a group of relevant taxa, the result is a linear line, where (log10) brain weight = a + b (log10) body weight. For a large array of primate data (e.g., Stephan et al., 1981), the slope of the line (b in the equation above) is about .76, and the correlation coefficient is .98, indicating that the relationship is almost perfect. This relationship will naturally vary depending on the databases and the transformations used. This is known as an allometric equation, and these are used frequently in biology to assess the underlying relationships between the size of parts of the body and the whole. The slope sometimes has an interpretation suggesting functional relationships between the brain and other variables. For example, in the above example, the slope is .76, extremely close to .75 or 3/4, which often describes a metabolic relationship (Martin, 1983). The slope of .666, or 2/3, has been championed by some (e.g., Jerison, 1973) as indicating an important geometric relationship

Table 1 Some fossil hominid brain volumes

Group	Number	Location	Average Brain volume	Range	Dating (My)
A. afarensis	3	E. Africa	435	385–500+	3–4
A. africanus	8	S. Africa	440	420–500+	2–3
A. aethiopicus	1	E. Africa	410	na	2.5
A. garhi	1	E. Africa	ca. 450	na	2.5

between volume and surface area. It is important to realize that these slopes vary depending on the taxa examined. In general, as the taxa become more similar, the slope decreases. Species within a genus generally have a slope around .3; within a species the slope is smaller yet, being about .2, and the correlation coefficient is also reduced (see also Martin and Isler, 2010).

Just as the human animal is curious, it is also vainglorious, always trying to find a measure that places it at the top. Thus we can fabricate a device, the *Encephalization Coefficient*, or EQ, which shows that relative to any database, the human animal is the most encephalized animal living. The point for *H. sapien*s shows a clear positive residual above the expected regression line, and in fact the human value is about three times that expected for a primate with its body weight. Table 2 provides a number of different equations based on differing databases, which happily give *H. sapiens* the highest value. (Actually, young immature dolphins will provide a higher number, but when compared to an immature human, the value is higher in the latter.) Two additional points should be made: (1) EQs are relative to the databases used, and thus there is an inherent 'relativity' to relative brain sizes; and (2) EQs do not evolve, only brain weight/body weight relationships do, and EQs are simply a heuristic device enabling comparisons between taxa; they have no reality outside of the database chosen, or species within a taxa, and are not designed to discuss within-species variation. For example, female humans are 'more' encephalized than males, given their smaller body sizes and smaller brains but the relationship might be simply a statistical artifact with no known behavioral manifestation given their nearly equal overall intelligence.

We will discuss later how the processes of hypertrophy and hyperplasia have been positively selected for in the course of the last 2 My of hominid evolution. (Hypertrophy refers to increases in size of the neural components, e.g., neurons, dendritic branching, nuclei, fiber tracts; hyperplasia refers to

Table 2 Some examples of encephalization quotients

Species	Brain wt. (g)	Body wt. (g)	EQ Homo[a]	EQ Jerison[b]	EQ Primates[c]	EQ Stephan[d]
Lemur	23.3	1400	21	1.56 (22.6)	.94 (32.7)	5.66 (19.6)
Baboon	201	25 000	28	1.97 (28.5)	.90 (31.3)	7.94 (27.5)
Gorilla	465	165 000	23	1.56 (22.5)	.61 (21.2)	6.67 (23.2)
Orang	370	55 000	31	2.15 (31.1)	.91 (31.7)	8.90 (30.9)
Chimp	420	46 000	39	2.63 (28.1)	1.81 (41.1)	11.3 (39.3)
Human	1330	65 000	100	6.91 (100)	2.87 (100)	28.8 (100)

Note: Each formula is based on a different set of data. The EQ Homo equation simply uses the average brain and body weight for *Homo sapiens*, and assumes an intercept where both brain and body weights are zero. The value of whichever animal is calculated is then given as a direct % of modern *Homo sapiens*. EQ Jerison is based on data for almost 200 mammals, while the EQ Primates is based on Martin, R.D., 1983. Human Evolution in an Ecological Context. American Museum of Natural History James Arthur lecture (1982), New York, data set for primates only. The EQ Stephan equation is based on insectivores only. The numbers in the parentheses are the % of the *Homo sapiens* value.
[a]Formulae: EQ Homo = Brain wt/1.0 Body wt$^{.64906}$.
[b]EQ Jerison = Brain wt/.12 Body wt$^{.66}$.
[c]EQ Primates = Brain wt/.0991 Body wt$^{.76237}$.
[d]EQ Stephan = Brain wt/.0429 Body wt$^{.63}$.

increased production of cells through mitotic division.) It is most probably the case that these processes are controlled by regulatory genes, and one of the major differences between ourselves and our closest nonhuman primate relative, the chimpanzee (brain size = ca. 385 g), relates to the schedules by which hyperplasia and hypertrophy are turned on and off during ontogenetic development (Holloway, 1979, 1995; Miller et al., 2012).

Brain Organization and Reorganization

It is well known that the brains of most animals are extremely similar to one another in terms of their overall organization, by which are meant neural nuclei and fiber systems. The human animal does not appear to show any different structures when compared to Old World monkeys such as the macaque, or the Great Apes, including the bonobo, chimpanzee, gorilla, and orangutan. Even the neural fiber tracts that are involved in human language appear in these primates (Deacon, 1997). One might ask, then, given the obvious species-specific repertoires that exist in all animals, how can these behaviors differ without differences in the underlying nervous systems? This is one of the major challenges of studying brain evolution, and in particular understanding what neural organizations account for the specificity of, say, human behavior, the ability to use language composed of arbitrary symbols. In other words, all mammals have cerebral cortex, thalamus, cerebellum, hypothalamus, and so forth, and basically these structures possess almost identical divisions of nuclei and do the same neural tasks. Clearly, brain size alone will never explain species-specific behavior, and the relationships between neural nuclei and fiber tracts will only go so far in explaining behavioral differences.

Allometric equations showing the relationship between one bodily component and the whole are instructive here. If we were to plot the logs (base 10) of primary visual cortex (PVC) against brain volume, we would find that the human PVC is 121% less than predicted, and similarly, the lateral geniculate nucleus of the thalamus is about 144% less than expected for a primate of our brain size. In contrast, if one were to plot the amount of cerebral cortex against brain weight, the result is a straight line, and the human point lies almost exactly on the line. In short, the human cerebral cortex is as large as would be expected for a primate of its brain size. But do portions of the cerebral cortex vary in size between different primates? In humans, the residuals mentioned previously suggest that compared to chimpanzees, the amount of PVC is significantly smaller in humans, or alternatively put, the posterior association cortex of the parietal and temporal lobes is relatively larger in humans. Since there are no essential differences between chimpanzees and humans in their visual abilities and competencies, these differences reflect selection for expanded functioning of the association cortex in humans. This is precisely what is meant by 'reorganization.'

When used in a comparative or evolutionary context, reorganization means changes in the sizes and proportions thereof of neural nuclei and their fiber tracts. Given that chimpanzees and hominids last had a common ancestor some 5–7 My, and that chimpanzees appear to have large PVC cortices, we infer that one aspect of human brain evolution has been some reorganization of the cerebral cortex, namely an increase in posterior association cortex (or, equally, a reduction in PVC) involved in polymodal cognitive tasks, where visual, auditory, and motor information are brought together in a synthetic whole. The trick, of course, is to demonstrate objectively when, where, and why these changes took place. This example of PVC has been purposefully chosen because one of the sulcal landmarks of the cortex that defines the anterior border of PVC is the 'lunate' sulcus, named for its crescentic shape, and there is some hope of identifying its position on some of the early hominid brain endocasts. In this regard, endocasts are most often frustratingly mute on other convolutional details.

Neuroanatomists have been trying for many decades to demonstrate the major differences between humans and other primates, and aside from gross brain size, very little has been shown. The frontal lobe, particularly its prefrontal portion, has been a favorite target, and, indeed, Brodmann (1909) claimed it was proportionally larger in humans, a view most recently championed by Deacon (1997). Unfortunately, other works have shown that the human brain has just as much frontal lobe as would be expected for a primate of its brain weight (Semendeferi et al., 1997; Uylings and van Eden, 1990), although the picture regarding prefrontal cortex has yet to be determined objectively using cytoarchitectonic criteria, which is how prefrontal cortex is differentiated from the pure motor cortex behind it (Schenker et al., 2010; Sherwood et al., 2003; Rilling et al., 2008). Hominid brain endocasts do not, alas, provide any sulcal landmarks with enough reliability to determine the boundaries of prefrontal cortex, which is so important to impulse control, and higher cognitive functions such as planning and abstraction. Thus these regions cannot be accurately measured in a phylogenetic sequence. The Neanderthals, living from about 300 000 to about 24 000 years ago, have frequently been described as having smaller frontal lobes; this is not based on objective measurements, but rather a perception that the large brow ridges on these humans were constraining frontal lobe development. Studying the Neanderthal brain endocasts and comparing them to modern humans, I have failed to see any significant difference between these two groups (Bookstein et al., 1999).

Similarly, regions such as 'Broca's and Wernicke's areas,' anterior and posterior association cortical regions involved in motor (Broca's) and receptive (Wernicke's) aspects of speech, are determinable on most fossil endocasts, and we can determine, for example, that Broca's region is more human-like on the brain cast of early *Homo*, some 1.8 My. This is the famous KNM-ER 1470 endocast of *Homo rudolphensis* from Kenya, which had a brain volume of 752 ml, but which may not be a direct ancestor to our own line of *Homo*. We know that Broca's regions in modern *Homo* are asymmetrical both in overall size and cytoarchitectonic divisions between areas 44, 45, and 47 of Brodmann (Schenker et al., 2010). Interestingly, Neanderthal endocasts show similar asymmetry in Broca's regions.

While the concept of reorganization has a heuristic value in directing our attention to changing quantitative relationships between different neural nuclei and fiber tracts, we cannot yet describe behavioral differences between closely related

animals such as the chimpanzee, gorilla, and orangutan, or different species of the genus *Macaca*, or indeed different breeds of dogs with their different temperaments, aptitudes, and sociality. We simply do not know what magic level of neural description is necessary to describe species-specific behavior. More recent research on prairie and mountain voles suggests that the difference in the females' ability to retrieve pups back to the nest depends on the distribution and number of neuroreceptors for the hormone oxytocin found in several nuclei of the brain, particularly the thalamus. Otherwise, their brains appear identical (Insel and Shapiro, 1992). In addition, it is necessary to remember that the brain possesses aspects of plasticity that we did not appreciate except within the past decade, and that as the brain's organization unfolds ontogenetically, interactions with environmental stimuli are always occurring, and the brain builds its organization partly through its plasticity. It is difficult enough to study and understand such patterns in laboratory animals, let alone in our fossil ancestors! While what has just been discussed suggests a somewhat pessimistic tone, we should remember that advances in noninvasive technology such as MRI, fMRI, PET, and tensor diffusion scanning have enormously increased our understanding of how the brain works, and how neural systems integrate and dissect data from the environment, always providing us with newer paradigms for further exploration about our brains and behavior, and in time, those of our closest relatives, the apes, in particular the bonobo and chimpanzee (see in particular Semendeferi et al., 2010).

Human Brain Asymmetry

The cerebral cortices of the human brain are usually asymmetrical, and tend to grow in a torque manner, reflecting minor differences in maturation rates. The hemispheres are seldom, if ever, equipotential in terms of functioning. Our left hemisphere is often characterized as 'analytic' and involved with language tasks, while our right hemisphere appears most competent in visuospatial integration, and is often thought of as the 'intuitive' or 'gestalt' hemisphere. These characterizations, while crude, hold up fairly accurately for right-handers and many ambidextrals. From radiographic studies, it was possible for LeMay (1976) to ascertain different petalia patterns for right- and left-handed humans with a high degree of precision. These petalias are small extensions of cerebral cortex that extend farther in one part of a hemisphere than on the other side. For example, we speak of a left-occipital right-frontal torque pattern of petalias as occurring with high frequency in right-handed individuals. This means that the left occipital lobe bulges somewhat more posteriorly on the left hemisphere, while the right hemisphere is somewhat broader in width in the frontal lobe. In true left-handers, who make up about 8–10% of human populations, the pattern is reversed, meaning they exhibit a right-occipital left-frontal pattern. Petalia patterns for a large collection of apes indicated that while chimpanzees, gorillas, and orangutans sometimes demonstrated asymmetries, they did not show the particular torque pattern described before as frequently. The gorilla, incidentally, was the most asymmetrical of the apes (Holloway and de LaCoste-Lareymondie, 1982). On the other hand, brain asymmetries, particularly in the *planum temporale* (temporal cortex) of the chimpanzee, show a strong left-hemispheric size difference compared to the right (Gannon et al., 1998). This is simply puzzling as we do not have any evidence that chimpanzees use this structure in communication as do humans, and the fact that we share this difference with chimpanzees suggests that brain organizational features relating to complex cognitive functioning has been around for at least 5–7 My. As our noninvasive scanning techniques become more sophisticated, we can expect to learn how these asymmetries function in animals other than ourselves. In fact, asymmetries appear in many animals and are hardly unique to primates. It is probably the degree of asymmetry that might be important in attempting to distinguish humans from other primates (Balzeau and Gilissen, 2010).

Hominid brain endocasts, when complete for both sides (unfortunately, this is very rare) allow the paleoneurologist to assess the cerebral asymmetries, and indeed, even australopithecines appear to show beginnings of the right-handed torque pattern found in humans, and, as one progresses through time, the petalia patterns become more accentuated in the modern human direction. If we add to these observations those of Toth's (1985) studies on the early stone tools of about 2 My, which strongly suggest right-handedness, this underlines the fact that our early ancestors' brains, despite their small size (sometimes within the extant apes' range), were reorganized, and that they probably had some modes of cognition very similar to our own.

Synthesis: Putting Together Size, Organization, and Asymmetry during Human Evolution

As mentioned earlier, human brain evolution has clearly been a process of integrating neurogenomic processes that led to increased size of the brain (hyperplasia and hypertrophy), and these neurogenomic changes also played roles in the reorganization (quantitative shifts) of neural nuclei, fiber tracts, and cortical cytoarchitectonics. In addition, it is probable that other changes occurred at the neurochemical level, involving neurotransmitters and receptor sites, but these are not well known from the comparative record, let alone the fossil one. This integration was sometimes gradual, sometimes 'punctuated,' at least based on the fossil hominid record currently available. The only reliable evidence from paleoneurology suggests that Brodmann's area 17 (PVC) was reduced early in hominid evolution, signs of the reduction being clear in *A. afarensis* some 3–3.5 Ma. While this would have meant a relative increase in posterior parietal cortex (area 39) and peri- and parastriate cortex (areas 18 and 19 respectively), the faithfulness of sulcal impressions does not allow for unambiguous definition of these areas. Similarly, it is not possible at this time to measure and delineate remaining areas of the temporal cortex and superior parietal lobule unambiguously. What is suggested, however, is that visuospatial abilities were most probably cognitively enhanced early in hominid evolution. It is not until we come to *Homo rudolfensis c.* 1.8 Ma that a case can be made for some frontal lobe reorganization in the third inferior frontal convolution, Broca's area. Thus it would appear there was a gradient of cerebral reorganizational changes starting posteriorly, and progressing anteriorly. Table 3 outlines these changes.

Table 3 Summary of reorganizational changes in the evolution of the human brain

Brain changes, reorganizational	*Taxon*
1. Reduction of primary visual striate cortex, area 17, and a relative increase in posterior parietal and temporal cortex, Brodmann areas 37, 39, 40, as well as 5 and 7	*Australopithecus afarensis, Australopithecus africanus*
2. Reorganization of frontal lobe (3rd inferior frontal convolution, Broca's areas 44, 45, 47)	*Homo rudolfensis;* early *Homo*
3. Cerebral asymmetries, left-occipital right frontal petalias	Australopithecines and early *Homo*
4. Refinements in cortical organization to a modern *Homo sapiens* pattern	*Homo erectus* to present

Note: (4) is inferred, as brain endocasts cannot provide that level of detail necessary to demonstrate the refinements in cortical organization from surface features alone. Areas 18, 19 are peri- and parastriate cortex just anterior to area 17, and are included in posterior association cortex here.

Table 4 outlines the major size changes in the human brain during its evolutionary odyssey. Paleoneurological data simply are not detailed enough to integrate the two tables of size and reorganizational changes into one holistic sequence of events. Basically, the paleontological record supports an early reorganizational change resulting in an increase in posterior cortex associated with visuospatial processing, perhaps accompanied by a relative small allometric increase in brain size from *A. afarensis* to *Australopithecus africanus*. This would correlate well with geological and paleontological evidence that shows that early hominids were expanding their ecological niches and becoming more diverse in their subsistence patterns in mixed habitats. We know this based on the fact that stone tool types are becoming standardized in form, tool inventories grow larger, and right-handedness is highly probable. With the advent of *Homo*, we find strong evidence for a major increase in brain size, both allometric (related to body size) and nonallometric, and a reorganized frontal lobe, broader, and showing a more modern human-like Broca's area. This suggests that indeed there had been some strong and dramatic selection pressures for a somewhat different style of sociality, one most probably based on a primitive proto-language that had some arbitrary symboling elements as the standardization of stone tools (e.g., Acheulean hand axes) increases, suggesting social cohesion and control mediated through symbolically based communication (Holloway, 1981). Needless to say, this is but one speculative account of the evidence. But from about 1.8 to roughly .5 Ma, we think there were minor allometric brain size increases to the earliest *Homo erectus* hominids of Indonesia and China, where brain sizes ranged from 750 to 1250 ml in volume. We have very little evidence for body sizes, but we believe, on the basis of the KNM-WT of 15 000 Nariokotome youth from Kenya at *c.* 1.6 Ma, that these did not differ significantly from our own.

This is also a time during which cerebral asymmetries are becoming more strongly pronounced. With the advent of Archaic *H. sapiens*, about .15–.2 Ma, we find brain sizes well within modern human values, and no evidence for further allometric increases, except possibly for the Neanderthal humans in which it can be argued that their larger brain and body sizes (lean body mass: bone and muscle) were adaptations to colder conditions (*see* Body, Evolution of). If further changes took place in cerebral and/or subcortical organization, they are simply not apparent from a paleoneurological perspective. Yet, the Upper Paleolithic is the time when cave art makes its appearance, and one cannot help but wonder whether the explicit use of art involving symbolization might not also have been the time for the emergence of language. In fact, however, there is nothing in the direct fossil evidence, and, in particular paleoneurology, that provides any evidence for such views. Claims for a single mutation are extremely speculative, and while some genes have been identified, such as FOXP2 (also found in Neanderthals), these also involve more general aspects of cognition. It is more likely that stone tool making and its underlying cognitive elements are very similar to

Table 4 Brain size changes in hominid evolution

Brain changes	*Taxon*	*Time (My)*	*Evidence*
1. Small increase, allometric[a]	*A. afarensis* to *A. africanus*	3.5–2.5	Brain endocast increase from ca 400 to 450+ ml.
2. Major increase, rapid, both allometric and non-allometric	*A. africanus* to *H. habilis, rudolfensis*	2.5–1.8	KNM–1470, 752 ml (300 ml increase)
3. Modest allometric increase in brain size to 800–1000 ml	*H. habilis* to *H. erectus*	1.8–.5	*H. erectus* brain endocasts and postcranial bones
4. Gradual and modest size increase to archaic non-allometric	*H. erectus* to *H. sapiens neanderthalensis*	.5–.075	Archaic *Homo H. sapiens*, Neandertal endocasts 1200–1700+ ml.
5. Small reduction in brain size among modern allometric	*H. sapiens* to *H. sapiens sapiens*	.015–present	Modern endocranial volumes

[a]Related to increase in body size only.

Academic Press, New York, pp. 189–200, and more recent endocast data, Holloway, R.L., Broadfield, D.C., Yuan, M.S., 2004. The human fossil record. In: Schwartz, JH, Tattersall, I. (Eds), Brain Endocasts: The Paleoneurological Evidence, vol. 3. Wiley-Liss, New York.

language, if not partially homologous (Holloway, 1969, 2012). Finally, it would appear that there has actually been a small reduction in brain size, probably allometric in nature, from about .015 Ma to the present (Henneberg, 1988; Hawks, 2012).

The totality of evidence shows that the brain has always been evolving during our evolutionary journey, with myriad changes taking place at different tempos during different times. As suggested recently (Holloway, 1997: p. 200):

> In sum, the major underlying selectional pressures for the evolution of the human brain were mostly social. It was an extraordinary evolutionary 'decision' to go with an animal that would take longer to mature, reach sexual maturity later, and be dependent for its food and safety upon its caretakers (parents?) for a longer period of time. The benefits for the animal were many, including a longer learning period, a more advanced, larger, and longer-growing brain, and an increasing dependence on social cohesion and tool making and tool using to cope with the environments that they encountered. Needless to say, language abilities using arbitrary symbol systems were an important ingredient in this evolution.

> The fossil record shows us that there was a feedback between the complexity of stone tools (which must be seen as a part of social behavior) and increasing brain size and the expansion of ecological niches. The 'initial kick', however, the process that got the ball rolling, was a neuroendocrinological change affecting regulatory genes and target tissue–hormonal interactions that caused delayed maturation of the brain and a longer growing period, during which learning became one of our most important adaptations.

These ideas have been detailed elsewhere (Holloway, 1967, 1969, 1979,1996, 2010), where more details may be found.

And to the Future?

There appear to be two common presumptions about our future brain evolution. One is that our biological evolution has stopped. The second is that our brains will continue to grow in size, with bulging frontal lobes (sort of a cross between E.T. and X-Files etc.), to handle our growing dependence on technology. What we have witnessed from the past fossil record is that our brains and bodies work largely in allometric fashion, and given the high metabolic cost of operating bigger brains (about 20–25% of our metabolic resources go to supporting our brains, which constitute only 2% of our total body weight), the second scenario seems highly unlikely. The first scenario is simply untrue, but it would require vast amounts of information from each generation of many living populations, something feasible perhaps, but not currently being collected. Furthermore, it is quite controversial whether brain size has any close relationship to intelligence, however intelligence is actually defined and measured. Recent research based on MRI determinations of brain volume and selected batteries of cognitive tests have shown correlations between test scores and brain volume ranging from .4 to .6. (Andreasen et al., 1993; Anderson, 2003; Davies et al., 2011). But if protein resources were to nosedive throughout the world for a significant period of time, selection would probably favor smaller body sizes in our species, and that could result in smaller brains, given an allometric relationship of roughly .3 between stature and brain size, at least in males (Holloway, 1980). While genetic engineering may well provide some respite between the ever-increasing mass of humanity and ecological and nutritive degradation, this too is likely to be nothing more than short-term fending off of the unstoppable future. These degradations are part and parcel of the human brain's capacity to ignore warnings that should curtail greed and stupidity. The paleontological record for most mammals suggests that at the taxonomic level of the genus (such as *Pan*, *Homo*, *Canis*, *Notocherus*, etc.), one finds a recognizable record of that genus spanning approximately 5–10 My. Our genus has thus far a duration of about 2 My. We, as a genus, despite our largish highly encephalized brains, have another 3 My to go if we wish to be as successful in the paleontological longevity game.

Brain: Response to Enrichment

Abstract

Enriched environments with opportunities for social and object interactions improve performance on complex behavioral tasks and the structure of the brain in rodents when compared with individuals housed alone or in small social groups. Although the largest changes can be seen in young animals, enrichment can induce plasticity at any point in the lifespan. Recent studies indicate that enrichment ameliorates neural problems and that the effects can be extended to primates, including humans.

In his now classic book *Organization of Behavior*, Donald Hebb described taking young lab rats home and letting his children raise them as pets. When these pet rats were later brought back to the laboratory for extensive training in the Hebb–Williams maze, they clearly outperformed cage-reared rats (Hebb, 1949). This charming anecdote (now it would be illegal) was meant to demonstrate the environmental effects on intelligence, which was one of the major points of Hebb's book. This led to a more systematic examination of environmental effects that can be accomplished in the laboratory through what is frequently known as an enriched environment or condition (EC). Although this environment can vary in different labs, there are common elements: group housing (rats and mice are social animals) in a larger than standard cage and the addition of objects ('toys') that are changed on a regular basis (**Figure 1**). These rats are then compared with either rats housed alone in standard cages (IC for individual, isolated or impoverished condition) or to socially housed (SC for social condition) rats in groups that usually contain fewer animals than in EC.

One could argue that the enriched environments are not really 'enriched' in comparison to the myriad environments that wild rats encounter. In general this is true, but the environment is being compared with laboratory conditions. However, this objection has led to the use of the term 'environmental complexity' for EC by some laboratories, including my own.

Figure 1 Rats exploring an enriched environment. In the Juraska laboratory 'toys' are changed daily. Note that the photograph was taken before wood was disallowed as part of the environment. The rats were healthy nonetheless.

The literature concerning use of enriched environments is large, and different uses have been found for the paradigm from demonstrating the malleability of the brain to exploring the therapeutic benefits of environmental stimulation. The current article cannot list all of these studies but is meant to trace the history of enrichment effects and cover the issues surrounding the paradigm to the present.

Behavior

Hebb's idea was followed up by many investigators who found that rats raised in stimulating conditions outperform rats in more standard environments in many types of mazes (Forgays and Forgays, 1952; Brown, 1968; Greenough et al., 1972; Juraska et al., 1984; Seymoure et al., 1996; Pietropaolo et al., 2006), discrimination reversals (Krech et al., 1962) and sequential alternations (Nyman, 1967). It is notable that rats from EC showed better performance on the Hebb–Williams maze even when rats from IC were handled every day (Greenough et al., 1972). This indicates that it is not the habituation to handling, generally part of EC, that is causing the superior performance. Several investigators found evidence that stimulated rats used spatial cues to solve the Hebb–Williams maze because their performance was more disrupted upon rotation of the maze compared with standard caged rats (Forgays and Forgays, 1952; Brown, 1968). This does not mean that stimulated rats inflexibly use distally spatial cues. The 17-arm radial maze involves baiting every arm with food (in the all arms-baited version), and ideally the rat visits each arm once in a daily session. Any arm that is revisited within a session is considered an error of working memory. Prior work from our lab found that rats from EC were more likely to solve the maze by using an adjacent arm strategy (response chaining) compared with rats from IC. This led to perfect performance by the end of training in some EC rats (Juraska et al., 1984; **Figures 2** and **3**). Thus, it appears that EC rats are flexible in the type of cues used depending on the

Figure 2 The errors for 2-day blocks of training on the 17-arm radial maze that were averaged for each environmental group and sex. There were significant differences between groups ($p < .001$) and days ($p < .001$) but no sex differences. Reproduced from Juraska, J.M., Henderson, C., Müller, J., 1984. Differential rearing experience, gender, and radial maze performance. Developmental Psychobiology 17, 209–215.

Figure 3 A graph illustrating that rats exposed to EC were more likely to choose an adjacent arm strategy in the 17-arm radial maze than were rats from IC. The probable position of the next arm chosen when point 0 is the given arm is plotted for rats from EC and IC (collapsed across sex). 75% of choices by EC rats were to an adjacent arm while the adjacent arm choice for IC rats was 36%. This led to fewer errors (**Figure 2**) committed by rats from EC. Plotted from data presented in Juraska, J.M., Henderson, C., Müller, J., 1984. Differential rearing experience, gender, and radial maze performance. Developmental Psychobiology 17, 209–215.

contingencies of the maze. More recently, Woodcock and Richardson (2000) found that rats from EC showed more contextual and discriminative ability. In contrast, tasks that are easily learned, such as black/white visual discriminations, often do not result in differential performances probably due to floor effects (Krech et al., 1962; Nyman, 1967). Depending on details of the procedure and the species/strain of rodent, exposure to EC can result in inconsistent results on the performance of the spatial water maze (Pietropaolo et al., 2006; Speisman et al., 2013) unlike the consistent benefits to performance on the more difficult Hebb–Williams and radial arm mazes.

The Brain

Effects on the brain were first noted by a group in Berkeley, headed by Mark Rosenzweig, who found that the weight of the cerebral cortex was greater in rats from EC than IC (Rosenzweig et al., 1962). The largest cortical difference was in the visual cortex which also was thicker in rats from EC than IC (reviewed in Bennett et al., 1964). Although modest (6–7%), this difference in cortical thickness has been replicated many times by the Berkeley group and in other laboratories (e.g., Juraska et al., 1985). It was also found that exposure to EC for as little as 2 h day^{-1} was sufficient to induce these changes (Rosenzweig et al., 1968). It should be noted that these experiments were all performed on male rats and the rare exceptions will be dealt with in a later section.

Controls

The relative ease of using cortical weight or the thickness of the visual cortex as an indicator of effects of enrichment led to a series of experiments by the Berkeley group that examined what aspects of the enriched environment were important for these effects. These are summarized in Bennett et al. (1964) and in several book chapters (e.g., Rosenzweig, 1971; Bennett, 1976). For example, enriched environments often include a running wheel among other objects, but running wheel activity alone did not produce the effects of EC. This was replicated by Zolman and Morimoto (1965). In addition, social experience alone is not sufficient to induce the neural or behavioral effects of EC on most measures. Many experiments contain an SC group and generally find it to be between the EC and IC groups. Social housing was further explored by Rosenzweig et al. (1978) in which the SC rats were in a group comparable in size to EC but did not achieve the EC brain effects. Interaction with objects in the environment appears to be essential. Rats that were in individual cages within the enriched environment were unable to interact with either objects or conspecifics and did not exhibit environmental effects. Likewise rats housed alone, but with objects, did not differ from rats in IC.

Thus, the interaction of both social housing and objects for exploration are necessary for the cerebral effects. The hypothesis that social interaction is arousing and leads to object interactions was further explored by the Berkeley group. They found that if an excitant drug was given to rats just before experiencing EC alone every day for 30 days, they did have a thicker cortex than rats in IC that had been given the same drug every day. It appears that a drug that increases arousal can compensate to some degree for the arousing presence of other rats (reviewed in Rosenzweig, 1971).

Another explanation for the effects of EC is that it is hormonal either through differential growth or stress. If EC causes accelerated growth, all parts of the body should mature faster. However, the increased weight of the brain in rats from EC is accompanied by smaller body weight and bone length (Diamond et al., 1965; Black et al., 1989). These dissociations indicate that the rate of maturation per se is not what is different between the groups. Evidence of differential stress effects have been more mixed with some studies finding no difference in adrenal weights (Bennett et al., 1964; Riege and Morimoto, 1970; Mirmiran et al., 1982; Black et al., 1989), while others find the rats from IC have larger adrenals than rats from EC (Geller et al., 1965; Krech et al., 1966; Uphouse and Brown, 1981). This discrepancy in IC may be due to more severe stress through early weaning, severe isolation and shipping of their pregnant mothers that were part of these studies. IC rats born to dams mated in the laboratory vivarium that are weaned after 21 days and handled periodically do not appear to be more stressed than EC rats.

The Visual Cortex

The largest cortical difference between EC and IC is in the visual cortex as documented many times by the Berkeley group. What cellular differences underlie the weight and thickness changes in the visual cortex? **Table 1** lists the many differences that have been documented in the visual cortex through the 1980s. All of these studies were in male rats exposed to the environments starting at weaning age until they were young adults (day 55–60). This paradigm shows that enrichment increases neural connectivity and the milieu (e.g., astrocytes, myelination, capillaries) that supports it.

Table 1 Cellular measures in the rat visual cortex in which enriched condition (EC) > isolated condition (IC)

Cellular variable	*Reference*
Dendritic branching	Volkmar and Greenough (1972)
Dendritic spine density	Globus et al. (1973)
Number of synapses per neuron	Turner and Greenough (1983)

Percentage of total tissue volume	
Capillary vessels	Black et al. (1987)
Astrocytic nuclei	Sirevaag and Greenough (1987)
Oligodendrocytic nuclei	Sirevaag and Greenough (1987)
Mitochondria	Sirevaag and Greenough (1987)
Number of unmyelinated axons in splenial corpus callosum	Juraska and Kopcik (1988)
Size of unmyelinated axons in splenial corpus callosum	Juraska and Kopcik (1988)

The Hippocampus

Initially, work on the effects of EC did not concentrate on the hippocampus because its thickness changes were smaller (2–3%) than in the visual cortex and less reliable. This is partially due to the rolled structure of the hippocampus which does not allow for standardized gross measurements in the same way that the laminar cerebral cortex does. Quantification of dendritic growth also indicated the male EC rats have almost no change in the dendritic tree compared with male IC rats in two major portions of the hippocampus: the dentate gyrus and CA3 (Juraska et al., 1985, 1989), although there are increases in spine density in some parts of the dendritic tree in CA1 (Moser et al., 1997).

Renewed interest in the hippocampus and EC was generated when Kempermann et al. (1997) found that mice from EC had more neurogenesis in the dentate gyrus and consequently, more neurons. Their enriched environment contained a running wheel, and this has led to the question of whether the aerobic exercise that a running wheel can provide is essential for the increased neurogenesis associated with EC. Other investigators have found separable behavioral effects for EC and exercise with each being beneficial (Pietropaolo et al., 2006). Kempermann et al. (2010) have reviewed the current evidence, and they conclude that the effects of a running wheel and other aspects of EC are additive. Aerobic exercise is more effective at increasing neurogenesis while EC itself increases the rate of survival of new neurons, giving each a major role. This was further confirmed by Birch et al. (2013) who found, in addition to increased neuronal survival, that EC without aerobic exercise increased NGF (nerve growth factor) and synaptogenesis in the hippocampus including the dentate gyrus. It becomes apparent that the lack of increased dendritic growth in the dentate in male EC rats previously reported (Juraska et al., 1985) was due to synaptogenesis being associated with new neurons rather than augmentation of existing neurons as in the visual cortex.

Sex

Historically, the vast majority of studies looking at the effects of EC and IC have used male animals. Even in a recent survey that includes the many studies that employ enrichment to ameliorate neural problems (see **Table 2**, the majority only examine

Table 2 Examples of improvement from environmental stimulation

Trauma	*Reference*

Models of brain disease	Pang and Hannan (2013)
Chronic neuropathic pain	Vachon et al. (2013)

male animals and only 17% look at both sexes (Simpson and Kelly, 2011)). However, the studies that have examined both males and females have often found different effects, both quantitative and qualitative, between the sexes. For example, the well-studied effect of increases in the size of the dendritic tree of the visual cortex in male rats in EC is not as pronounced in female rats, where neurons from two of the three cortical layers sampled had smaller EC-IC differences in females than males (Juraska, 1984; **Figure 4**). In the granule neurons in the dentate gyrus, on the other hand, females from EC had larger dendritic trees than those from IC, while the environment did not affect the dendrites in males (Juraska et al., 1985). The pattern was even more complicated in hippocampal CA3 which receives major input from the dentate granule neurons. Within these neurons, there were sex differences in reaction to the environment that varied between different portions of the dendritic tree (Juraska et al., 1989). One interesting correlate of these sex differences is that females in EC have a more pronounced rise in brain-derived neurotrophic factor (BDNF) than males in EC (Bakos et al., 2009).

Figure 4 The dendritic length of two portions of the dendritic tree (basilar and apical oblique dendrites) of pyramidal neurons in the rat visual cortex. In both portions of the dendritic tree, there was a significant sex by environment interaction, so that males had larger differences due to the environment than females. The direction of this finding is the opposite of what was seen in the hippocampal dentate gyrus. Plotted from data in Juraska, J.M., 1984. Sex differences in dendritic response to differential experience in the rat visual cortex. Brain Research 295, 27–34.

The splenium of the rat corpus callosum carries axons between the two sides of the visual cortex almost exclusively (Kim et al., 1996). Given the greater plasticity in the rat visual cortex of males compared with females, it is interesting that in addition to the EC-IC differences listed in **Table 1**, female rats also had an increase in the number of myelinated axons following exposure to EC and male rats did not (Juraska and Kopcik, 1988). There are no simple generalizations about sex differences and the cellular effects of EC. It is obviously important to understand more of the mechanisms involved in the differences between the sexes in cellular plasticity to the environment.

Age

Both the starting age and the duration of enriched environments vary considerably between studies. However, cellular (dendritic) changes can be detected in as little as 4 days of exposure when rats have been exposed to EC immediately after weaning (Wallace et al., 1992). The greater plasticity of juvenile and adolescent rats may mean that the age of first exposure is relatively more important than duration. Most studies start enrichment at less than 2 months of age (Simpson and Kelly, 2011) which capitalizes on the growth and pruning that the adolescent brain continues to undergo (Juraska et al., 2013). It has been established that the dendritic tree is larger in the visual cortex in EC compared with IC rats when the environments are started in adulthood (after 4 months of age) (Uylings et al., 1978; Juraska et al., 1980), although the difference between EC and IC is not as great as in rats that are exposed starting at weaning (Volkmar and Greenough, 1972). Introducing adult males to group living is far more stressful than it is at weaning (Juraska, unpublished personal observations) which may contribute to this discrepancy.

The plastic cellular changes in adult rats in response to an enriched environment open the possibility that enrichment might help to ameliorate the effects of aging. The cortical thickness increases seen in younger animals in response to EC have also been documented in aged (2+ years old) rats (Diamond et al., 1985). Middle (15 months) to aged (24 months) rats also show increases in the cortical dendritic tree following EC (Green et al., 1983; Kolb et al., 2003). More direct comparisons of compensation for aging effects have been done. Through the use of an aged group examined at the time of initiation of the enriched environment, Greenough et al. (1986) demonstrated that the loss of dendritic branches on cerebellar Purkinje neurons during aging are halted in aged rats placed in EC. Likewise, Saito et al. (1994) found that a decrease in synaptic density in the cortex with age can be reversed by EC exposure, as can the age-related decrease in hippocampal neurogenesis, even if EC does not contain a running wheel (Speisman et al., 2013). Reviews covering details on behavioral and neurotransmitter effects of EC during aging are available (Frick and Benoit, 2010; Mora et al., 2007).

Applicability to Primates, Including Humans

At the time of Hebb's work in the 1940s and the Berkeley group's in the 1960s, the idea that enriched environments increased intelligence and even altered the structure of the

brain was considered radical. Neural plasticity in response to the environment was in its infancy. Today, the profound role of the environment on both the brain and behavior is widely accepted, including and importantly, for humans. At least some of this change in the attitude of both the scientific community and the general public is due to work on EC/SC/IC in rats. It has been bolstered by cellular evidence from primates exposed to more stimulating environments (Floeter and Greenough, 1979; Kozorovitskiy et al., 2005). The noninvasive structural magnetic resonance imaging (MRI) technique and the unfortunate circumstances of many infants and young children in institutionalized care have brought the evidence into the human realm as well (Sheridan et al., 2012). The importance of environmental stimulation has also become important as the human population ages (Volkers and Scherder, 2011). The systematic study of environmental stimulation changed how society views the human condition.

EC as Therapy

Now that the basic tenets of environmental stimulation and neural plasticity have been accepted, most current studies have applied EC as a therapy to improve both behavioral and neural outcomes in models of a wide array of disorders. A sampling of these is listed in **Table 2**. On the whole, environmental stimulation ameliorates every neural problem examined. The increases in several neurotrophin levels (i.e., growth factors) that result from exposure to enriched environments in many neural regions could be part of the explanation (Ickes et al., 2000). More details on the mechanisms whereby EC mitigates neural trauma can give clues for therapies.

From another vantage point, the improvement that almost always accompanies exposure to enrichment casts doubt on the validity of our animal models where rodents, in particular, live in barren, and often asocial, conditions. The lesson that the enriched condition taught us was that environmental experience is an important component in how the brain works and in behavioral performance. We need to apply this lesson to our animal models more widely.

Brain Stimulation Reward

Peter Shizgal, Concordia University, Montreal, QC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In 1953, Olds and Milner discovered that rats would readily learn to work for electrical stimulation of certain brain sites. Their findings inspired a large body of research on the neural basis of reward, motivation, and learning. Unlike consummatory behaviors, which satiate as a result of ingestion of and contact with the goal object, performance for rewarding brain stimulation is remarkably stable and persistent. Pursuit of the stimulation is enhanced by different classes of dependence-inducing drugs, suggesting that common neural mechanisms underlie the rewarding effects of drugs and electrical brain stimulation. Indeed, dopamine-containing neurons in the midbrain are implicated in both phenomena. Major schools of thought that have addressed brain stimulation reward (BSR) differ with regards to the roles played by hedonic experience and craving, although there is substantial overlap between the different viewpoints. A tradition that arose in the study of machine learning has been brought to bear on the role of dopamine neurons in reward-related learning in animals and on the phenomenon of intracranial self-stimulation. Neuroeconomic perspectives strive to integrate the processing of benefits, costs, and risks into an account of decision-making grounded in brain circuitry. Adjudication of the differences between the various viewpoints and progress toward identifying the relevant neural circuitry has been hindered by the lack of specificity inherent in the use of electrical stimulation to study central nervous system function. Many neurons in addition to those targeted are likely activated by such stimulation. Recently developed optogenetic methods may overcome this obstacle, providing much more specific means for stimulating or silencing populations of nerve cells selected on the basis of their gene expression, cell-body location, and projections. Coupled with behavioral methods of increasing sophistication and specificity and with quantitative modeling of signal flow in the relevant neural circuitry, the new optogenetic methods promise to bring us much closer to fulfillment of the hopes engendered long ago by the discovery of BSR.

The Discovery and Its Context

Brain stimulation reward (BSR) was discovered in 1953 by James Olds and Peter Milner (Olds and Milner, 1954; Milner, 1989; Olds, 1973). They had come to McGill University to work with D.O. Hebb, inspired by his groundbreaking theoretical work. In contrast to the dominant behaviorist orthodoxies of the day, which isolated psychology from the emerging disciplines of neuroscience and cognitive psychology, Hebb's views linked brain, mind, and behavior.

New findings and ideas about the neural bases of motivation and reinforcement provided a rich context for the discovery of BSR (Valenstein, 1973). For example, the demonstration that lesions of different hypothalamic nuclei could lead either to massive overeating or starvation contributed to a seminal, physiologically based theory of motivation (Stellar, 1954). During that era, English-speaking investigators became familiar with Hess' use of electrical stimulation to map the hypothalamic control of autonomic outflow and behavior (Hess, 1949). Among Hess' observations were stimulation-elicited responses suggesting states of rage or fear. Shortly before Olds and Milner's discovery, Delgado, Roberts, and Miller (Delgado et al., 1954) showed that cats would learn to escape electrical stimulation of certain deep forebrain structures. Another key component of the context was research linking brain stem circuitry to the control of arousal and vigilance (Moruzzi and Magoun, 1949). The pattern of connections between nerve cells in the brain stem region of interest was seen as netlike ('reticulated'); thus the region was dubbed the 'reticular formation.'

At the time that Olds joined Hebb's group, Milner and Seth Sharpless, another graduate student, had developed a theory linking reticular activation to positive reinforcement, the process by which desirable outcomes strengthen the behaviors that produce them. Their experimental tests of this idea proved disappointing: The rats tended to avoid locations in a maze where stimulation of the reticular formation had been delivered.

A strikingly different reaction was noted in a rat prepared by Olds. The electrode had somehow missed its reticular-formation target and ended up instead in the basal forebrain. This subject returned repeatedly to the location where stimulation had been delivered. As the experimenters altered the rewarded location, the animal's behavior changed accordingly, and it directed its searching toward the site where it had most recently hit pay dirt. Olds then succeeded in training the rat to press a lever that triggered delivery of the stimulation. This animal worked indefatigably to stimulate its own brain. Such behavior has since been termed 'intracranial self-stimulation' (ICSS), and the effect that causes the animal to seek out the stimulation is called 'BSR.'

In the initial report published by Olds and Milner (Olds and Milner, 1954), they presciently discuss their findings "as possibly laying a methodological foundation for a physiological study of the mechanisms of reward." Indeed, their paper was a wellspring for thousands of subsequent experiments.

Why did the report by Olds and Milner have such a large and enduring impact? Perhaps paramount is the promise their results offered that psychological phenomena such as learning, reinforcement, and motivation could be investigated fruitfully by physiological means. The authors also pointed out that the phenomenon of BSR could be used to distinguish between competing behavioral theories. For example, a prominent theory at the time held that reinforcement arose from the

reduction of a drive, such as the abatement of hunger. This view is not easily reconciled with the fact that rewarding stimulation of many sites arouses the animal rather than calming it and that stimulation of some BSR sites can also induce sated animals to engage in consummatory behaviors such as eating and drinking (Margules and Olds, 1962; Hoebel and Teitelbaum, 1962).

The Phenomenon

The behavior of the self-stimulating rat is striking to behold, particularly in the case of electrodes arrayed along the medial forebrain bundle (MFB). When the rewarding stimulation is strong and easily triggered, the rat attacks the lever with singular focus, pressing repeatedly and forcefully at high rates. This behavior is remarkably persistent. For example, a rat working for MFB stimulation maintained an average response rate above 2000 presses per hour over a continuous 26-hour period (Olds, 1958a). Rats have been shown to cross an electrified grid (Olds, 1958b) or to gallop uphill along a runway, leaping over hurdles (Edmonds and Gallistel, 1974) in order to access a lever that triggers delivery of the stimulation. When food was provided uniquely in an ICSS chamber in which strong stimulation was available, rats worked for the electrical reward in lieu of feeding and thus starved themselves (Routtenberg and Lindy, 1965).

Why would an animal work so assiduously for a reward that has no evident biological value? It has long been suspected that the neural activity triggered by the stimulation mimics some aspects of natural rewards. Indeed, MFB stimulation is as good an economic substitute for food and water as they are for themselves (Green and Rachlin, 1991), and the rewarding effect of such stimulation both competes and summates with the rewarding effects of sweet (Conover and Shizgal, 1994a) or salty (Conover et al., 1994) solutions. The incompleteness of the mimicry may give rise to some of the differences between BSR and natural rewards. Unlike performance for natural consummatory rewards, ICSS does not result in the accumulation of a substance in the body, which may explain why the appetite for stimulation does not satiate. Similarly, the electrical reward bypasses peripheral receptors for taste, smell, and touch, which may explain why the accumulation of nutrients in the gut undermines the rewarding effect of a gustatory stimulus (sucrose) more severely than the rewarding effect of MFB stimulation (Conover and Shizgal, 1994b).

The nature of the rewarding effect elicited by electrical stimulation may vary both across and within brain sites. For example, food or water deprivation can alter preference between stimulation of different brain sites (Gallistel and Beagley, 1971), and the potentiating effect of chronic food restriction is seen only at some MFB sites (Blundell and Herberg, 1968). Moreover, the fat-signaling hormone, leptin, has opposite effects on self-stimulation of different brain sites, depending on whether or not the rewarding effect is sensitive to chronic food restriction (Fulton et al., 2000).

Anatomy and Neurochemistry

The sites where BSR can be produced occupy a substantial proportion of the brain volume (Wise, 1996). Positive sites are distributed from the olfactory bulbs, at the front of the brain, to the nucleus of the solitary tract, at the back, and are found both in cortical and subcortical regions of the forebrain. The best-characterized sites lie along the trajectories of the MFB and of fibers coursing near the midline of the brain stem. In both cases, the neurons that carry the reward-related signal away from the electrode tip include cells with relatively fast-conducting, longitudinally oriented, myelinated axons (Shizgal, 1997; Miguelez and Bielajew, 2004). This characterization narrows the field of plausible candidates, but it leaves open multiple possibilities. The recent technical innovations described in the last section of this article hold great promise for the long-sought identification of these neurons.

Several neurotransmitter systems are implicated in BSR. There is a large body of evidence tying dopamine-containing neurons to the rewarding effect (Wise and Rompré, 1989). ICSS is potentiated by manipulations that enhance transmission in these cells and weakened by manipulations that decrease dopaminergic neurotransmission. Recently, Witten, Steinberg, and their coworkers demonstrated that rats will work for direct optical activation of midbrain dopamine neurons (Witten et al., 2011). The dopamine-containing neurons that project from the ventral tegmental area of the midbrain to the nucleus accumbens, a structure at the base of the anterior forebrain, are thought to play a particularly important role in BSR as well as in the effects of natural rewards such as food and water. Mice have been shown to self-stimulate for direct optical activation of excitatory inputs to the nucleus accumbens from glutamate-containing neurons in other forebrain structures (Stuber et al., 2011; Britt et al., 2012).

Although ventral tegmental dopamine neurons play a crucial role in BSR and project to forebrain structures via the MFB, their axons are difficult to excite under the conditions of ICSS experiments. Instead, or in addition, the rewarding effect may well arise from activation of inputs to the ventral tegmental dopamine neurons (Shizgal and Murray, 1989; Shizgal, 1997; Moisan and Rompré, 1998).

Acetylcholine-containing neurons in the pedunculopontine and laterodorsal tegmental nuclei play a role in BSR, are activated transsynaptically by rewarding MFB stimulation (Yeomans et al., 2000; Rada et al., 2000), and provide excitatory input to ventral tegmental dopamine neurons (Forster et al., 2002). Mice will work to disinhibit dopamine neurons in the ventral tegmental area via a disynaptic GABAergic pathway arising in the bed nucleus of the stria terminalis in the basal forebrain (Jennings et al., 2013), and there are multiple pathways employing glutamate as a neurotransmitter that provide excitatory input to the ventral tegmental area from forebrain and brain stem structures (Geisler et al., 2007).

Like ICSS self-administration and abuse of drugs entail the copious expenditure of behavioral resources in pursuit of an objective that appears worthless or detrimental to biological fitness. A full account of the neural circuitry responsible for ICSS is likely to provide insight into how dependence-inducing drugs attain their powerful influence over behavior and decision-making. Performance for BSR is enhanced by many drugs that are both self-administered by laboratory animals and subject to abuse by humans (Wise, 1996). The dominant hypothesis concerning these effects is that the drugs in question alter dopaminergic neurotransmission directly or indirectly.

Much recent work on ICSS and reward seeking is directed at inputs to ventral tegmental dopamine neurons or to their postsynaptic targets, which must be considered as possible substrates of drug action in addition to the dopamine neurons themselves.

Schools of Thought

Theoretical accounts of ICSS have emphasized different aspects of the phenomenon. However, the differences are often less marked than the contrasting labels for the theories suggest.

Hedonic

An early article on ICSS in *Scientific American* bears the provocative title: "Pleasure Centers in the Brain" (Olds, 1956). When someone first observes a self-stimulating rat, they typically speculate that the stimulation 'makes the rat feel good.' It seems commonsensical that one would tend to repeat an activity that produced pleasurable consequences. The converse, however, is far from clear. Does the fact that an activity is repeated necessarily imply that it generates a positive hedonic state? Will the activity be repeated if, and only if, it is pleasurable?

Pleasure implies awareness, a faculty believed to depend on resources in short supply, such as attention and working memory. It would be highly maladaptive to pass all signals controlling action through such a narrow processing bottleneck. Thus, contemporary depictions of the control of action place most of the burden on distributed processes operating below the waterline of awareness (Baars, 1988; LeDoux, 1996). On that view, the repeated pressing of the lever does not necessarily imply a positive hedonic state (Shizgal, 1999).

Theorists who have ventured onto this slippery terrain have typically been more circumspect than the labels for their theories might suggest (Wise, 1982, 2008; Kringelbach and Berridge, 2009). Their task is not easy. On the one hand, they cannot ignore reports from early studies of human patients who voluntarily self-administered electrical stimulation to sites homologous to those that support ICSS in laboratory animals. These accounts include descriptions of pleasurable experience (Sem-Jacobsen, 1959; Heath, 1964). On the other hand, some have contested the interpretation of the verbal subjective reports from these studies of human patients (Kringelbach and Berridge, 2009), and we lack the means to infer the subjective experience of nonhuman animals. Moreover, subjective pleasure and persistent operant responding for rewards have been dissociated in studies of human participants (Lamb et al., 1991).

Seeking and Craving

If a path to the lever is blocked by an obstacle, the self-stimulating rat will seek another. Such flexible approach to a goal is typical of what psychologists call appetitive behavior, and it contrasts with the more stereotyped patterns observed once the animal procures a natural goal object, such as food, and begins to consume it. Potentiation of flexible approach figures heavily in several different accounts of the ICSS phenomenon. Although Wise applied the psychiatric term, anhedonia, to his theory of why reductions in dopaminergic neurotransmission attenuate ICSS, drug self-administration, and operant performance for natural rewards, the core of his formulation concerns what he calls 'motivational arousal,' a state that promotes flexible reward seeking. His theory differs from several others in that he views subjective pleasure as a normal, but not obligatory, concomitant of the motivational arousal engendered by exposure to rewards. In contrast, the incentive-sensitization hypothesis of Robinson and Berridge (1993; 1998) portrays the ICSS phenomenon as a manifestation of what they call 'wanting,' a process that endows stimuli with the ability to seize attention and to promote anticipatory, flexible approach (Ikemoto and Panksepp, 1999). They argue that dopaminergic neurotransmission is essential to 'wanting' but not to a contrasting component of reward that they term 'liking.' When 'liking' impinges on consciousness, it is experienced as pleasure. It is also manifested in consummatory behavior so that we ingest foods that we like and eschew foods that we do not. The subjective states of rats are hidden from us, but their ingestive behavior is not. Thus, Berridge and his coworkers use 'liking' in quotation marks to describe behavior that they believe to arise from the neural underpinning of hedonic states, whether these states are experienced or not. Experimenter-delivered stimulation of ICSS sites fails to strengthen ingestive patterns and may weaken them, a finding that these theorists take to reflect a dissociation between 'wanting' and 'liking.' Although this interpretation has been contested (Wise, 2008), the distinction between wanting and liking has been highly influential, particularly because of its correspondence to the self-reports of long-time drug users who evince continued cravings but claim that the drug no longer generates euphoric effects. Indeed, in studies of human participants, partial blockade of dopamine synthesis reduced drug craving without systematically undermining self-reported euphoric effects (Leyton et al., 2007).

Reinforcement Learning

Self-stimulation of many brain sites is acquired quickly, and the behavior typically extinguishes rapidly once the reward is no longer delivered. This rapid reinforcement learning is among the most striking aspects of the ICSS phenomenon, and it has played a prominent role in theoretical accounts. During the 1990s, the confluence of work in machine learning and electrophysiology cast the reinforcement-learning aspects of ICSS in a new light.

In their quest to develop intelligent machines, researchers came to appreciate that much of the knowledge required to solve real-world problems cannot be specified in advance. The environment is not entirely predictable, and its complexity is effectively without limit. Under such conditions, it is desirable to imbue machines with the ability to learn about the consequences of their actions and the relationships between events. The algorithms developed to meet these objectives share important properties with formulations developed by students of animal learning while extending the quantitative rigor and scope of those ideas (Sutton and Barto, 1998). One such algorithm, called temporal-difference learning, entails moment-to-moment updating of predictions concerning future rewards and comparison of these predictions to the

rewards actually received. Discrepancies between predictions and outcomes, called temporal-difference errors, cause reward predictions and the associated reward-seeking actions to be modified and improved.

Montague, Dayan, and Sejnowski recognized a striking correspondence between the properties of temporal-difference errors and the activity of midbrain dopamine neurons observed by Schultz and colleagues during Pavlovian and operant conditioning experiments carried out in monkeys (Montague et al., 1996; Schultz et al., 1997). They proposed that this correspondence could account for the ICSS phenomenon. According to this view, the brief burst of ('phasic') firing in midbrain dopamine neurons that is triggered by electrical stimulation constitutes a temporal-difference error that alters weights in the neural networks encoding the value of the reward-seeking actions and the predictions associated with response-related cues. In effect, the self-stimulating rat is portrayed as the victim of a hallucination of value. Although the stimulation produces no homeostatic or reproductive benefit, cues that predict it and the actions that procure it come to be represented as increasingly valuable due to the reward-prediction errors it generates.

A problem with the original formulation of the prediction-error hypothesis of ICSS is that the weights increase progressively with delivery of successive stimulation trains and should saturate eventually regardless of the strength of any suprathreshold stimulation train; saturation would be achieved rapidly in the case of strong trains and more slowly in the case of weaker ones. This prediction does not jibe well with the finding that rats systematically choose higher strength trains in preference to weaker ones, even after extensive experience with the stimulation (Simmons and Gallistel, 1994). The evidence that midbrain dopamine neurons are activated transsynaptically by MFB stimulation (Shizgal, 1997) can rescue the hypothesis: an inhibitory input representing the reward prediction could come to counteract the transient activation produced by the stimulation train, reducing and eventually eliminating the prediction error. Such a nulling effect should be much less likely in the case of optical stimulation, which can excite the dopamine neurons directly. Substituting optical for electrical stimulation could provide a powerful test of the hypothesis that induced bursts of firing in dopamine neurons are the cause of the observed reward-related learning.

Neuroeconomic

The study of the neural basis of decision-making and the evaluation of the benefits, costs, and risks on which choices are based has come to be called neuroeconomics (Glimcher and Rustichini, 2004; Loewenstein et al., 2008). The first papers written from this perspective were accounts of ICSS (Shizgal and Conover, 1996; Shizgal, 1997), and it has been argued that there is a striking correspondence between the neuroeconomic approach to ICSS and some core ideas in economics, judgment, and decision-making (Shizgal, 2012). The neuroeconomic approach shares with the reinforcement-learning approach a commitment to quantitative models that can be tested by means of behavioral and neural measurements. One distinction between the approaches concerns the phase of the experiment that is of primary interest. The reinforcement-learning approach focuses primarily on how relationships between events and contingencies between actions and their consequences are learned. In contrast, neuroeconomic experiments typically begin with a subject that has already learned a task. In the case of ICSS, such work has focused (1) on the psychophysical transformations that translate objective variables, such as the strength and cost of rewards, into their subjective equivalents, and (2) on the stages of processing at which particular neural populations contribute to the computation of reward value (Hernandez et al., 2010). That said, the reinforcement-learning approach has been extended to address the issue of reward-related costs; whereas this approach links reward-related learning to phasic firing of dopamine neurons, effort costs have been related to more slowly varying, tonic levels of dopamine (Niv et al., 2007).

Methodological Issues and Emerging Directions

Biophysical Specificity

Studies employing electrical stimulation of the central nervous system have been plagued by a lack of biophysical specificity. The stimulation typically activates a set of neurons of unknown composition in addition to the population targeted by the experimenter. This is the principal reason why the directly stimulated neurons that give rise to the rewarding effect have proved so difficult to identify. The recent development of optogenetic methods promises to circumvent the lack of specificity inherent in electrical stimulation methods while retaining all of the principal advantages (Deisseroth, 2010; Yizhar et al., 2011).

Using optogenetic methods, neural activity can be silenced or induced on timescales as short as that corresponding to single nerve impulses and as long as the actions of many drugs. These effects can be restricted to specific neural populations targeted on the basis of conditional gene expression, cell-body location, and axonal projections. The optical component of optogenetic technologies consists of two elements: molecules that transduce light into cellular signals and a mechanism to deliver appropriate photic stimuli to the targeted cells. The transducer molecules are opsins, the class of proteins that render photoreceptors sensitive to light. Unlike vertebrate opsins, which compose part of a multistage chain of complex chemical reactions, microbial opsins are far simpler, functioning directly as light-gated ion channels or pumps that alter the movement of electrical charge across the cell membrane so as to either promote or suppress the generation of neural signals. The genetic component of optogenetic technologies consists of methods for inserting microbial opsin genes into the genome of neurons, restricting the expression of these genes to specifically targeted cell populations and promoting trafficking of the protein products of these genes to the cell membrane. Fine fiber-optic probes implanted in the brain are used to deliver light at a wavelength selected for optimal capture by the microbial opsin. Optogenetic methods are complemented by molecular neuroanatomical techniques for labeling and visualizing specific populations of neurons.

The initial attempts to train rodents to perform operant responses to obtain optical stimulation of ventral tegmental

dopamine neurons were only moderately successful. In one case (Adamantidis et al., 2011), mice could be trained to lever press only if food was delivered along with the laser illumination; however, operant performance was subsequently maintained by optical stimulation alone, albeit at low response rates. In a second study (Kim et al., 2012), mice were successfully trained to nose poke for optical stimulation of ventral tegmental neurons but again, response output was low. In contrast, rats expressing channelrhodopsin2, an excitatory opsin, in dopamine neurons respond in a vigorous, sustained manner for optical stimulation of the ventral tegmental area (Witten et al., 2011). This work and associated studies in which specific inputs to ventral tegmental dopamine neurons were manipulated optogenetically (Britt et al., 2012; Jennings et al., 2013) demonstrate the promise of the new methods to overcome technical obstacles to determining the neural underpinnings of reward seeking.

Behavioral Specificity

Another challenge to achieving an adequate neurobehavioral account of ICSS and of reward seeking in general arises from what can be called 'multistage causal convergence.' There are many possible reasons why a laboratory animal may choose to perform an operant response. The various processes that can support such responses are likely composed of multiple stages. For example, the decision to press a lever may arise from the separate computation of benefits, costs, and risks, the folding together of the results of these computations into a unitary estimate of value that is compared with estimates of the values of other available actions, and the translation of the winning estimate into reward-seeking actions. When the proclivity of the animal to press the lever is altered by a neural manipulation, how is one to know which of the possible causes of lever pressing has been affected and at what stage of processing? Answering such questions requires that the specificity and power of behavioral measurement methods match those of the promising new methods for optical stimulation, optical silencing, and neuroanatomical visualization.

Work employing a neuroeconomic approach provides an example of the increasing specificity of new behavioral methods and the multistage nature of the processes underlying ICSS. It has long been known that psychomotor stimulants boost performance for BSR, an effect that been attributed to a drug-induced increase in the sensitivity of reward-related circuitry (Crow, 1970). This hypothesis was tested by means of a multistage model of ICSS coupled to a behavioral testing paradigm that can distinguish the signatures of drug action at different stages of processing (Hernandez et al., 2010). According to this model, the effect of the volley of action potentials triggered by the rewarding stimulation is integrated according to an aggregate rate code; reward strength is represented by the number of firings within a time window, integrated across neurons. This count is transformed nonlinearly into a subjective representation of reward intensity (Simmons and Gallistel, 1994) and then combined with information about reward cost and probability so as to yield an estimate of the payoff from lever pressing. If psychomotor stimulants increase the sensitivity of the circuitry to electrical activation, these drugs should lower the number of firings required to produce a reward of given intensity. By measuring ICSS as a function of both the strength and cost of rewarding stimulation, Hernandez and colleagues showed that cocaine enhances reward seeking primarily by other means, such as a reduction in subjective reward cost or amplification of the output of the circuitry performing the integration (Hernandez et al., 2010).

Emerging Directions

Optogenetic experiments on reward seeking are typically complemented by electrophysiological measurement of neural activity. Integration of these approaches with increasingly specific behavioral testing methods and with quantitative modeling in the reinforcement learning, psychophysical and neuroeconomic traditions may address many of the problems that have hindered progress in the study of ICSS and of the neural basis of reward seeking. This would provide a solid foundation for testing competing accounts of how goals are evaluated, selected, and sought, and how information about benefits, costs, and risks is learned, used, and abused.

Acknowledgments

The author's research on brain stimulation reward has been supported by the Canadian Institutes of Health Research, the Natural Science and Engineering Research Council of Canada, the Fonds de Recherche du Québec (Santé), and the Concordia University Research Chairs program. Brian Dunn, Daniel Palacios, and Sarah Nolan-Poupart provided helpful comments on the article.

Breast-feeding: Effects on Cognitive and Neural Development

Fahmida Tofail and Jena Hamadani, International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Abstract

Breast milk is a complete, natural food for the baby that addresses both growth and brain development of the growing infant through many different pathways. Although research findings from both developed and developing countries reported comparatively smaller benefits of breastfeeding on children's brain development, almost all the studies consistently showed a beneficial trend. Assessing intelligence and brain development is not straight forward and can be influenced by a multitude of factors. In this article, we have reported the association of breastfeeding on neuro-cognition of children under the light of published research findings. The review highlighted that breastfeeding is indisputably important for neuro-cognitive development, along with other health and economic advantages. So, promotion of exclusive breastfeeding up to 6 months and its continuation until 24 months of age, along with appropriate complementary feeding need to be strongly encouraged.

Breast milk is a complete, natural food for the baby. Besides being of nutritional value, it plays a vital role in the neurocognitive development of the growing infant directly as a result of improved nutritional status of the infant and indirectly by providing psychosocial care and child-friendly environment for learning. Several longitudinal and cross-sectional studies have shown consistent beneficial effects of breastfeeding on children's cognitive development and intelligence; however, the effects are small and sometimes not significant. In this article, we report the association of breastfeeding on neurocognition of children under the light of published research findings.

Overall development of a child is widely influenced by factors like health, nutrition, exposure to toxicants, cognitive stimulation, mental state of the caregivers, and exposure to violence (Walker et al., 2011). With great disappointment, it is reported that over 200 million children from low- and middle-income countries of the world are failing to reach their full potentials due to multiple risk factors, e.g., stunting, micronutrient deficiency, and poor stimulation. Breastfeeding was identified as one of the protective factors for child development (Walker et al., 2011). The term 'child development' refers to progression of a number of domains that include physical, cognitive, motor, language, emotional, and behavioral development. None of these domains alone can describe a child. However, in this article we will mainly discuss association of breastfeeding with neurocognitive development of children.

Cognition and Neuronal Development

In general, cognition indicates a complex higher-order mental ability necessary for survival, i.e., understanding and adaptation with one's surrounding world. These abilities include mainly thinking, reasoning, learning how to manipulate the environment, and problem solving (Vasta et al., 2004; Goswami, 1998). Growth of the brain starts *in utero* and most of the brain cells are formed before birth. Development of the brain following birth is a prolonged process and interactions with the environment modify the connections between the brain cells or neurons. During early infancy, massive brain growth involves increase in neuronal connections (synapses), nerve fibers (dendrites), and fiber bundles along with their covering of fatty sheaths (myelination). All these neuronal development contribute to child development. There is a general consensus that by 2 years of age the brain structure simulates the overall appearance of the adult brain and by 3 years all main fiber tracts are visible. However, myelination of nerve fibers continues for a longer period of time and is related with nutrition (Matsuzawa et al., 2001; Paus et al., 2001).

Breastfeeding

The World Health Organization (WHO) and UNICEF recommended exclusive breastfeeding (EBF) up to the age of 6 months and continued breastfeeding along with appropriate complementary foods until 24 months of age (WHO/UNICEF, 2003).

The following rules were recommended by the WHO, as a joint WHO/UNICEF statement for every facility that provides maternity services and care for newborn infants.

Have a written breastfeeding policy that is routinely communicated to all health care staff.

1. Train all health care staff in skills necessary to implement this policy.
2. Inform all pregnant women about the benefits and management of breastfeeding.
3. Help mothers initiate breastfeeding within half an hour of birth.
4. Show mothers how to breastfeed and how to maintain lactation even if they should be separated from their infants.
5. Give newborn infants no food or drink other than breast milk, unless medically indicated.
6. Practice rooming-in – that is, allow mothers and infants to remain together – 24 h a day.
7. Encourage breastfeeding on demand.
8. Give no artificial teats or pacifiers (also called dummies or soothers) to breastfeeding infants.
9. Foster the establishment of breastfeeding support groups and refer mothers to them on discharge from the hospital or clinic.

Breastfeeding not only contributes to better growth and development of children, but also influences the physical and mental health of mothers. Breast milk is considered the best food for young infants because of its nutritional, anti-infective, and antiallergic properties. It also has contraceptive and economic advantages for the mother and family. It enhances mother–child

interactions and reduces maternal stress and depression by providing beneficial hormones. Combination of all these factors lead to improved childcare and facilitates child development. The possible beneficial effect of breastfeeding on the child's neurocognition remains a matter of great scientific interest.

Different Terminologies Used to Define Breastfeeding

In the 1960s and 1970s, 'exclusive breastfeeding' used to mean providing breast milk to the child as the only source of milk with or without foods other than milk.

The current, globally accepted definitions of breastfeeding, developed by the WHO and the UNICEF, are modifications of definitions earlier set by the 'WHO Global Data Bank on Breastfeeding' (WHO, 1996), which focuses on the well-being of the mother–infant pair (Table 1).

Mechanism of Action of Breastfeeding on Cognitive and Neurodevelopment

It is suggested that breastfeeding can affect cognition and neurodevelopment both directly and indirectly. The two main mechanisms and the possible pathways to improved cognition and neurodevelopment as a result of breastfeeding are discussed.

Nutritional Effects

Breast milk is natural first food for newborns and is unique in its composition as it contains all the macro and micronutrients, hormones, and immune components that an infant requires until 6 months of life for optimum growth and development. Thereafter, it continues providing half or more of nutritional requirement of child until the second half of infancy and up to a third during the second year of life.

Breast milk contains fat, protein, carbohydrate, and minerals. The calorie content is about 60–75 kcal/100 mL which is sufficient for the healthy growth of the child's organs including the brain. Casein is its main protein constituent. In addition, it contains alpha-lactalbumin, lactoferrin, immunoglobulin A (IgA), lysozyme, and serum albumin. Colostrum is rich in protein content and provides immunity to the newborn that protects the child from common childhood illnesses, e.g., measles, diarrhea, pneumonia (Wang and Wu, 1996). A healthy child has a greater chance of exploring the environment and learning through interaction with surroundings. Hence, the anti-infective and antiallergic properties of breast milk can indirectly promote neurocognitive development. Breast milk is an important source of essential fatty acids like linoleic acid and alpha-linolenic acid and provides polyunsaturated, long-chain fatty acid (PUFA). PUFA plays a major role in the structural development of retinal photoreceptors, neurones, and synaptic membranes. It carries out certain functions for improving neurogenesis and synaptogenesis like ion transport, receptor activity, enzyme action, and membrane fluidity (Banapurmath et al., 1996). Through the above actions it enhances visual and cognitive development (Mitmesser and Jensen, 2007). In addition, breast milk contains hormones like choline, taurine, and various peptides and polysaccharides. Choline helps in proper communication between nerves and muscles and therefore increases processing speed. Taurine is a membrane

Table 1 Different terminologies of infant feeding

Category of infant feeding	*Definition*
Breastfeeding	Child receives breast milk directly from the breast or expressed breast milk.
Exclusive breastfeeding	The infant receives only breast milk from mother or a wet nurse, or their expressed breast milk, but no other liquids or solids with the exception of drops or syrup formulations of vitamins, mineral supplements, or medicines.
Predominant breastfeeding	Breast milk is the major source of nourishment; however, child also receives water and/or water-based drinks (e.g., sweetened and flavored water and tea); fruit juice; oral rehydration solution (ORS), drop and syrup formulation of vitamins, minerals and medicines, and limited quantities of ritual fluids. With the exception of fruit juice and sugar water, no food-based fluid is allowed.
Full breastfeeding	Exclusive breastfeeding and predominant breastfeeding together constitute full breastfeeding.
Artificial feeding	Infant receives only artificial feeds and no breast milk at all.
Partial breastfeeding	Infant receives some breastfeeds and some artificial feeds, milk, cereal, or other foods.
Complementary feeding	Infant receives both breast milk and timely introduced appropriate semisolid or solid food(s).
Bottle-feeding	Infant receives liquid or semisolid food from a bottle with a nipple/teat.

WHO, 1996. Global Data Bank on Breastfeeding. World Health Organization, Geneva.

stabilizer and antioxidant and is involved in the development of visual and the central nervous system (Reynolds, 2001). Leptin, a hormone in breast milk, through its regulatory acts on hypothalamic–pituitary–adrenal axis, reduces stress in newborns. It is also hypothesized to contribute to learning and memory of young infants through the hippocampal development of brain (Walker et al., 2004). Recently, a small experimental study reported the possible role of a brain-derived neurotrophic factor (BDNF) in breast milk on neurons of central and the peripheral nervous systems. BNDF plays an important role in supporting the survival, growth, and differentiation of neurons and synapses. In the developing brain, it is active in areas vital for learning, memory, and higher thinking ability, particularly in cerebral cortex, hippocampus, and basal forebrain. BNDF also has an association with long-term memory and contributes to neurocognition (Nassar et al., 2011).

Psychosocial Effects

Breastfeeding indirectly promotes neurocognition of children through its effects on maternal well-being and mother–child interaction. The emotional warmth and consistency of the relationship with the mother, particularly the quality of attachment is important for emotional development of the child. Children develop attachment to their mothers during the first 6 months of life. Bowlby (1982) described attachment as the feeling of security that the infant seeks when under stress. A secure child, after a period of separation from its mother, demonstrates lesser resistance and can be easily calmed and comforted upon return of the mother. On the other hand, an insecure child may demonstrate avoidant or ambivalent response. The avoidant child after separation from the mother may not become distressed and does not seek to contact her when she returns. The ambivalent child wants to contact the mother but remains upset even after being reunited following a period of separation (Benoit, 2004). As the mother interacts closely with the child while breastfeeding, the child develops a secure attachment helping her/his emotional development and allows explorative behavior for learning (Gordon, 1998). Lactating mothers have higher levels of prolactin and oxytocin compared to nonlactating mothers. In animal models, these hormones have been associated with feelings of calmness, well-being, and nurturing behavior (Walker et al., 2004). Thus, benefits to mothers who breastfeed include reduced postpartum depression, workload, reduced chance to become pregnant, and increased emotional bonding. Breastfeeding also contributes to physical well-being of mothers by reducing the risk of ovarian and breast cancers. This, in turn, facilitates positive mother–child interactions leading to better childcare and child development.

Research Findings Related to Breastfeeding and Neurocognition

A good number of studies, mostly from developed countries, have examined the link between breastfeeding and child development. Here, we present important findings from relevant reviews and meta-analyses reported till 2011 and independent reports published after 2011.

In 1999, Grantham-McGregor et al. (2007) documented 22 articles published during 1929–98, which examined the developmental advantages of breast-fed over bottlefeed children. The studies demonstrated a small but consistent benefit of breastfeeding on children's development. Among older children aged 18–24 months, there were significant developmental advantages from breastfeeding even after adjustment for socioeconomic variables, particularly if they were exclusively breast-fed for at least 3 months. Studies that examined the long-term developmental effects in 4- to 18-year-old children observed consistent developmental benefits in breast-fed children but the effect quantum depended on other factors such as size at birth, poverty, and duration of breastfeeding. Interestingly, there was a detrimental effect of EBF for longer than 12 months, but not when breastfeeding was continued along with complementary feeds.

A meta-analysis on articles published between 1966 and 1996 found that even after adjusting for probable covariates, breastfeeding was significantly associated with higher cognitive score compared to formula feeding (Anderson et al., 1999).

Another review on studies published between 1966 and 1998 could not draw any firm conclusion on the cognitive benefits of breastfeeding although the trend of higher score was still in favor of breastfeeding (Drane and Logemann, 2000).

Jain et al. (2002) reviewed articles published between 1929 and 2001 and concluded that breastfeeding promotes intelligence.

Another review article by Rey in 2003 discussed breast feeding related cognitive findings from earlier retrospective studies, large birth cohorts, meta-analysis, critical reviews, and individual studies on full-term infants and low birth weight infants. The review highlighted a wide range of disparities among the studies and concluded that the beneficial effects of breast milk on infants' cognitive development could not be clearly recognized from these studies.

A meta-analysis by Der et al. (2006) on the studies conducted in developed countries on full-term breast-fed babies adjusting for maternal IQ and other socioeconomic factors did not find significant benefit of breastfeeding on children's cognition.

The latest *Lancet* series on child development however reported strong evidence on the benefits of breastfeeding on children's development and school achievement (Walker et al., 2011).

Since the above article that reviewed publications till 2010, we could locate seven papers published on the relationship of breastfeeding to neurocognitive development of children born at full term.

Out of these seven studies, only one was cross sectional, conducted among Irish school children at the age of 9 years using the propensity score matching (PSM) analysis (McCrory and Layte, 2011). The outcome measure was 'academic test scores' and information on breastfeeding was based on parental recall. Although the study showed a robust benefit, the finding can be confounded by recall bias.

Among the other six cohort studies, one was from a middle-income country that prospectively followed the Krakow birth

Table 2 Studies on breastfeeding and cognition in the years 2011 and 2012

Study, type, and location	*Study population and age*	*Developmental assessment tool*	*Result for adjusted models*
McCrory and Layte, cross-sectional study, Ireland (2011)	8226 school children at 9 years	Children's academic test scores	Breast-fed children had 3.24 ($p < .001$) and 2.23 ($p < .001$) percentage points higher scores on reading and mathematics, respectively, compared to those who were never breast-fed
Paterson et al., cohort of Pacific infants, New Zealand (2011)	1018 children, 2 years	Australian developmental screening test	35% had developmental delay. Breastfeeding <6 weeks was identified as one of the risk factors for developmental delay
Guxens et al., population-based cohort study, Spain (2011)	504 children assessed at 14 months	Bayley scale of infant development	Cumulative intensity of EBF during the first year of life was linearly and positively associated with 0.37 points; higher mental development score duration of EBF was also associated with higher mental development score of 0.37 points
Boutwell et al., early childhood longitudinal study, birth cohort, UK (2012)	3700 children (2700 breast-fed; 1000 nonbreast-fed) assessed at 9 months and 2 and 4 years	Bayley Short Form-Research Edition (BSF-R) mental scale	Significant difference between groups (mean difference = 1.92, $p < .05$)
Quigley et al., United Kingdom millennium cohort study, UK (2012)	11 101 term babies born at 37–42 weeks of gestational age assessed at 5 years	British ability scales tests (naming vocabulary, pattern construction, and picture similarities subscales)	A two-point increase in score for picture similarities (when breast-fed ≥4 months) and naming vocabulary (when breast-fed ≥6 months)
Jedrychowski et al., Krakow prospective birth cohort study, Poland (2012)	468 term babies (>36 weeks gestational age) assessed at 1, 2, 3, 6, and 7 years	Bayley scale of infant development up to 3 years age. Wechsler intelligence test (WISC-R) for 6 and 7 years	EBF for 3 months had 2.1 points; EBF for 4–6 months had 2.6 points; and EBF >6 months had 3.8 points; higher IQ scores compared to the others
Borra et al., Avon Longitudinal Survey of Parents and Children (ALSPAC study), UK (2012)	12 268 children assessed at 5, 7, 11, and 14 years	Key Stage 1 Battery: language, reading, reading comprehension, writing, spelling, and mathematics. Key Stages 2 and 3: English, mathematics, and science	Breastfeeding is associated with higher tests scores, about one-tenth of standard deviation

cohort in Poland at 1, 2, 3, 6, and 7 years of age. Developmental assessment was done using the Bayley Scale of infant development (BSID) for the younger group and the Wechsler intelligence scale for children-revised (WISC-R) for the older age group. After controlling for a large number of confounders, including maternal IQ, the effects of breastfeeding on cognitive development of children was sustained through 7 years of age (Jedrychowski et al., 2012).

The remaining five studies were all from developed countries: three from United Kingdom, one from Spain, and one from New Zealand (**Table 2**). Paterson et al. (2011) conducted an observational study on a cohort of children at 2 years of age. He found a large percentage (35%) of children to be developmentally delayed in one of the five domains of Australian Developmental Screening Test. It was noted that breastfeeding for less than 6 weeks was one of the risk factors for developmental delay among Pacific children. In a nonexperimental study using Bayley Short Form-Research Edition (BSF-R) mental scale on children at 9 months and 2 and 4 years, the cognitive function of breast-fed children was significantly higher than that of nonbreast-fed children by PSM analysis (Boutwell et al., 2012). A birth cohort follow-up in UK showed significant benefit in breast-fed children compared to those who were never breast-fed after adjusting for all possible confounders (Quigley et al., 2012). Breastfeeding was shown to be beneficial in Spanish children tested at 14 months using the Bayley scales (Guxens et al., 2011). In a large longitudinal cohort, the ALSPAC study, benefit of only 0.1 SD was found in children's cognitive development assessed at 5, 7, 11, and 14 years using a battery of English reading and writing, mathematics, and science (Borra et al., 2012).

Despite wide variations in the design, population, site, test measures, and confounders in the above-mentioned studies, all of them consistently show a trend of positive association of breastfeeding with neurocognition.

Conclusion

Breastfeeding is very important for providing ideal food for proper growth and neurocognitive development of young infants. Besides nutritional value, breast milk is a rich source of hormones, enzymes, and antibodies that are protective for the

child's health and development. Breastfeeding also contributes to mother–child interaction and to effective parenting by reducing maternal depression and improving maternal well-being. This helps in efficient bonding that allows enhanced neuronal connections.

Although the results from both developed and developing countries reported comparatively smaller benefits of breastfeeding on child development, all the studies consistently showed a beneficial trend. It is possible that the use of different assessment tools, their adaptation in different countries, adjusting for confounders, wide variations in the design, small sample size in some studies, operational definitions of breastfeeding, and age of assessment complicated the interpretations in many ways. Moreover, long-term consequences were seen in very few studies. Longitudinal studies are important as some of the developmental domains become measurable in later ages.

Moreover, intelligence can be influenced by a multitude of factors and it is not easy to control for those factors while analyzing data. Although several of the recent studies made efforts to control a number of known confounding factors, there could be other, as yet unidentified factors that could influence the outcome. It is also unethical to conduct randomized trials on breastfeeding and thus prospective, observational studies are the possible choices to determine the impact of breastfeeding on cognitive development of children. In view of the trends in benefits of EBF on cognition, and other advantages of breastfeeding including its cost-effectiveness, nutrient value, protective properties from infections and well-being of both mother–child dyads, promotion of EBF up to 6 months and its continuation until 24 months of age, along with appropriate complementary feeding, need to be done in developing countries.

Abstract

One of the markers of contemporary studies in the humanities and social sciences is the close, critical attention directed onto the mass media and popular culture. British cultural studies, emerging out of the expanded English university system in the 1970s, were among the first to develop and broadly disseminate the methodologies and approaches which made such attention possible. Focusing initially on the relations between language and ideology through the close analysis of media texts, before diversifying into a broad range of interdisciplinary activities – cultural theory, cultural history, ethnography, media studies, and the analysis of the social construction of gender, race and identity – British cultural studies has played a fundamental role in establishing the conceptual and theoretical agenda for studies of popular cultural forms and practices.

The Analysis of Popular Culture

Academic disciplines in the humanities and social sciences took some time to accept the need to understand properly the power and influence of the mass media in Western societies. The spread of a transnational commercial popular culture, apparently disconnected from specific local cultures and disseminated through advertising and marketing, was seen by many in the academy as a threat to traditional or civilized values which should simply be repudiated. Within the British university system until the end of the 1960s, the task of analyzing and evaluating popular culture had been taken on by the discipline of English. However, the methods supplied by training in literary studies were suited for making esthetic and moral distinctions that proved inappropriate as a means of understanding the appeal of popular cultural forms such as film, television, or popular music. It was gradually acknowledged that popular cultural forms served a very different social function for their audiences than that served by high art for its audiences. Cultural studies was a product of the consequent recognition of the necessity of finding new ways of understanding the specific social functions of popular culture. Although it was partly a product of literary studies, the methods it developed had to be very different.

The starting points for this project are usually seen (Turner, 1996) to be Richard Hoggart's account of the clash between an 'organic' English working class culture and mass mediated popular culture, *The Uses of Literacy* (1958), and Raymond Williams' history of cultural change in an industrializing England, *Culture and Society 1780–1950* (1958). The debates generated by these books set the conditions within which Hoggart established the Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham in 1964. In 1968, he was succeeded as Director of the CCCS by Stuart Hall, who played a major role in developing methods of analysis for popular cultural forms over the next two decades. In particular, Hall's work during the 1970s provided a very important conduit through which theoretical developments from France, by Barthes around post-Saussurean semiotics and by Althusser around the workings of ideology (Hall, 1977), reached an English readership.

Initially, the analyses of popular culture which emerged from this tradition were highly political critiques of the ways ideology was embedded in language. Close analysis of media 'texts' (specific examples of media practice exposed to detailed study) was employed as means of explaining how social understandings were carried and reinforced by the mass media, and how these social understandings were structurally inclined to be those supported by the state or the interests of market capitalism (Hall et al., 1978). However, by the latter half of the 1980s, British cultural studies had distanced itself from the notion that the media was simply a means of reinforcing the ideological interests of capital or the state. Instead, it had acknowledged the alternative possibilities suggested by such writers as Dick Hebdige (1979) during the late 1970s and began to investigate how popular cultural forms might also serve the interests of those who consume them. This produced a more positive reading of popular culture, and a more nuanced and contingent set of expectations about the specific interests served by popular cultural forms at particular historical conjunctures (Fiske, 1987). Among the results of this focus over the 1980s was a significant expansion of the field, as a broad range of studies of television, popular music, the print media, fashion, media audiences, and youth subcultures were published, and as cultural studies established itself at undergraduate and graduate level in universities in the UK, the USA, Canada, Australia, and elsewhere. As the various forms of cultural studies proliferated (borrowing methods from history and anthropology as well as literary studies and sociology), the relative distinctiveness of the British tradition began to dissipate.

By the early 1990s, this reorientation of the field and modes of analysis had exposed cultural studies to the accusation of 'cultural populism' (McGuigan, 1992): of complicity with the media and cultural industries that reduced its capacity to provide a critical analysis of the interests these industries served. This provoked a further reassessment of the study of popular culture which served to reassert the complicated set of understandings required: to understand how popular cultural

forms worked as communication; to understand the competing political potentials implicit in the consumption of popular culture; and to understand how the political economy of the media and cultural industries operates as a determining frame around the relations between producers and consumers.

Crucial to the development of the analysis of popular culture within this tradition has been the focus on the media product as a 'text,' and the complementary insistence on the importance of understanding the processes through which these texts are consumed by audiences.

Texts and Audiences

The idea of treating media products as 'texts' comes from literary studies but the early means of doing so came from semiotics (see, for example, *Semiotics*). Semiotics was especially useful for two reasons. First, while it was interpretative as well as descriptive, it did not produce an aesthetic or moral evaluation of the text and was thus differentiated from the only other discipline where textual analysis was highly developed – literary studies. Second, it was the first method which offered the means for analyzing all forms of communication – written, verbal, and visual, either singly or in conjunction with other forms. As a result, semiotics enabled the detailed and comparatively objective analysis of popular cultural products such as advertising, television news, and newspaper layouts.

For most of the 1970s and much of the 1980s, British cultural studies busied itself with developing modes of textual analysis from a combination of semiotics, certain aspects of film theory, and Althusserian theories of ideology. The interest in the text was initially in critically unraveling its carriage of ideology. This slowly gave way to an attention that was more intrinsically interested in the text or genre of texts under examination – the appeal of soap opera, for example, or the construction of the news. Such work initially assumed that the readings generated by the cultural studies critic were immanent in the text, repeating an elitist assumption also made within literary studies that the critic had a privileged insight into what the 'true meanings' of popular culture might be.

The flaws behind this assumption were addressed by a number of interventions, the most significant being Hall's argument that the process of encoding or producing the text was separate and different from the process of decoding or 'reading' the text (1980). Indeed, he argued that there were at least three kinds of reading positions consumers might take when decoding the text. Consumers might simply accept what was described as the 'preferred' meaning; that is, the meaning apparently preferred by the producers or senders of the message or what is often referred to in the literature as the 'dominant' meaning. They might take an 'oppositional' position, which flatly rejects or subverts what they nevertheless would recognize as the preferred reading in order to construct their own, alternative reading of the message. Or they might produce a 'negotiated' reading, developed out of a relatively complicated consideration of the preferred reading and its alternatives. Hall's schema emphasized the contingency of the act of consumption, the varying ways in which audiences might understand any text. In practice, it was accepted, most would develop a negotiated reading rather than either of the other two options. This also emphasized how individualized the processes might be through which culture constructs its meanings. Consequently, cultural studies began to focus on these broader cultural processes rather than the processes of the texts themselves; this in turn was a shift away from the opinion of the critic and towards a serious consideration of the evidence from the audience.

Research into audiences' understanding of texts had occurred within the CCCS during the late 1970s, and the Centre's interest in subcultures had also produced a number of studies which used the methods of ethnography as a means of investigating how subcultural groups made sense of their social experiences (Hobson, 1980; Willis, 1977). However, it was not until Ien Ang's innovative analysis of fans of the US soap opera, *Dallas* (1985), that audience studies began the process of becoming a fundamental component of the practice of cultural studies. Ang's study used the letters from a group of *Dallas* fans both as texts to be analyzed and as ethnographic evidence which helped substantiate the nature of the soap opera's appeal to, for instance, intelligent and educated women who, at that time, would not have been reckoned to belong to the target audience for that kind of television. Something of an explosion of audience studies occurred, usually claiming to be in some way 'ethnographic' (that is, in this context, involving some direct observation of the group under analysis). The appropriation of what was a much reduced version of their research methodology provoked stern critiques from social science disciplines where the established protocols of ethnography were taken more seriously and employed more rigorously.

While the trend for what one might call 'thin' ethnography eventually waned, the usefulness of ethnography as a means of examining not only media audiences but other cultural formations has been accepted in cultural studies. David Morley (1986, 1992) moved audience studies away from largely providing a complementary strategy for those trying to understand the workings of media texts, and situated it as a means of, for instance, understanding the function of television within the home, and its implication in the web of social relations involving age and gender that made up families' everyday lives (*see* Audiences, Media).

Representation and Identity

While the above account might imply that cultural studies' interest in the text has been displaced by the focus on audiences, there is at least one area where that is not true. Textual analysis in cultural studies was initially almost an end in itself; the development of a process which could unpack the construction of meaning within, particularly, media texts was rightly seen as a significant methodological advance. As a result, for quite some time, the performance of textual analysis was a dominant genre of research and writing within the literature of the field. As the authority of the critic was challenged by audience studies, however, the point and practice of textual analysis had to change.

Cultural studies had always been interested in how the world was 're-presented' to us in other forms: as images, as sounds, as writing, and as narrative. The influence of post-structuralist theories of language and culture situated representation as our only access to the real: we understood the world through languages, and through the ways in which it is represented to us. The problem of culture for many, therefore, is overwhelmingly the problem of representation.

One of the shifts in approach emerging from the mid-1980s interest in the audience was a focus on how cultural identity was represented. Feminist cultural studies was the primary instigator here, with its emphasis on how women's lives were determined and constrained by the dominant representational patterns within which the feminine is constructed (Franklin et al., 1991). The interest in identity as a contingent product of representation, and of the need for minority groups to therefore regard their representation as a political issue, becomes a major concern for cultural studies theory and a major genre of textual analysis.

It is also probably the location where the two complementary streams of British cultural studies – on the production and textual side, and on the consumption or audience side – have been most effectively and productively combined (Hall, 1997). The focus on the representation of particular minority groups, and the interrogation of the effect of that representation upon particular examples of those groups, is precisely the territory that feminist cultural studies has developed. It has also been taken up by other groups – gays and lesbians, ethnic and racial minorities, diasporean communities – as a means of understanding the construction of their identities, and of contesting the political effects of that construction through a critique of the representational patterns involved. Finally, in the 1990s, the focus on representation has assisted in opening up the issue of the construction of national identity for British cultural studies.

The Politics of British Cultural Studies

One of the ways in which British cultural studies have conceptualized their project is to see it as inherently political. That is, British cultural studies set out to understand how culture works in order to intervene in that process and produce change. Williams, Hall, and other key figures were identified with New Left Marxism, and had played the roles of activitists within British politics. The process of developing the field, the work of 'theoretical clarification,' as it was called, has routinely addressed the problem of how to make academic knowledge matter within contemporary party politics. Indeed, when Hall (1988) addressed the problem of the Left's incapacity to combat the working class alignment with (then) Prime Minister Margaret Thatcher's policies, he presented it as an issue both for party policy and cultural theory.

The centrality of politics to the British cultural studies project is among the factors which may still differentiate it from those more recent cultural studies traditions which have developed, for instance, in the USA. Indeed, among the concerns expressed by Hall and others about the success British cultural studies achieved in exporting itself to the USA at the end of the 1980s was the likely displacement of politics from the theoretical field. The widespread pattern of institutionalization of cultural studies, in the UK and elsewhere, has also been proposed as a threat to this fundamental principle. Similarly, if a little paradoxically given its direct engagement with political institutions, the incorporation of cultural studies academics into the process of state policy formation, particularly in the UK and Australia, and the consequent interest in the related field of cultural policy studies (Bennett, 1998), has been criticized as a form of co-option.

The politics of British cultural studies itself is not without its blind spots, of course. It was reluctant to admit feminist concerns and paid little attention to issues of race, ethnicity or nationality until the 1990s. Its resistance to empirical research methods has exposed it to criticism from within the social sciences. However, its determination to make a highly theoretical enterprise prove itself in the material world of practical politics continues to mark it out as a distinctive intellectual and social project.

Editor's Note

As Turner's original entry makes clear, cultural studies is a field of critical thinking and literary criticism that emerged in the UK in the late 60s and early 70s and is focused largely on mass media and popular culture. Although work in the "cultural studies" tradition now goes on around the world, the British tradition remains an intellectually vibrant area of study. Contemporary works in this tradition would include: Brantlinger, 2013[1999]; Jin, 2011; Hughson, 2011. Turner's essay also notes that cultural studies was "reluctant to admit feminist concerns." Today, there is an identifiable literature of feminist cultural studies; see, e.g., Clarke and Olesen, 2013 [1999]; Torres 2013.

Abstract

Donald Broadbent's World War II experiences of deficiencies in engineering translated into a lifelong commitment to what was then the emerging field of Applied Psychology. After studying under Frederick Bartlett at Cambridge, Broadbent went on to an appointment with the UK Medical Research Council Applied Psychology Research unit at Cambridge and subsequently to an MRC appointment at Oxford. Throughout his career he addressed, with colleagues, a range of related topics including auditory attention, the effects of fatigue and noise as well as extroversion and introversion on attention, the roles of errors and lapses in production systems, and information processing in management systems. Perhaps his greatest achievement is reflected across these works in the respect that he garnered for the value of applied psychology.

Donald Broadbent described a boyhood troubled by sharply fluctuating family fortunes, the early loss of a father whose talents greatly exceeded his educational and social opportunities, and the determination of his mother that Broadbent should transcend similar problems by gaining a scholarship to a prestigious public school, Winchester. There he found the physical sciences dispiriting because of the volume of existing knowledge to be mastered before any original work was possible. He was called up to the Royal Air Force, where pilot training in the USA forced recognition that poor engineering design causes catastrophic human errors. Also that, in a far richer society than postwar Britain, these problems were being addressed by an emerging profession of Applied Experimental Psychology to which he, too, might aspire. A brief wartime course in engineering had arguably provided the skills and mind-set that developed his understanding and empathy with this particular slant on psychology. So, when he resumed his interrupted undergraduate career at Pembroke College, Cambridge, against the strong advice of his tutors he read psychology in Sir Frederick Bartlett's Department of Experimental Psychology.

This was then, arguably, the best possible place in the world for him. Bartlett, and the talented staff he had appointed, had distinguished themselves in applied human factors research and personnel selection during the war, and so gained respect from other scientists for what was then, misunderstood by Government circles as an insignificant pseudoscience. The Cambridge Department was uniquely in the mainstream of new ideas. Broadbent has described it as intellectually 'explosive,' similar to that in the Cavendish laboratories and the 'Bun Shop' pub just across Downing Street, where DNA was being discussed. Among the volatile ingredients were the immediate local legacy of Kenneth Craik's seminal applications of control theory to human performance, William Hick's use of Shannon and Weaver's new information theory to model decision-making and his interpretation of its use in the recent wartime work of Egan, Garner, and Pierce; the beginnings of speculative computational neuropsychology in Hebb's (1949) "Organisation of Behaviour," and demonstrations by Grey Walter and Ross Ashby that automata theory could simulate and explain the behavior of simple organisms. After gaining a first-class degree, Broadbent had to explain to Bartlett that he could not afford to follow his advice to support himself independently to work on any problem that interested him. So he was appointed as a member of scientific staff at the Medical Research Council Applied Psychology Research Unit (APRU) in Cambridge, which Bartlett had founded and Norman Mackworth then directed. The APRU was funded to solve applied problems for government agencies, principally the Royal Navy, who determined the research agenda. Mackworth asked Broadbent to work on noise, both as an obstacle to effective speech communication and as a factor in attentional distraction, arousal, and stress. Noise became a main theme of Broadbent's research, from his first paper, "Some effects of noise on visual performance" in 1951, to a concluding review, "Human Performance and Noise," published with Dylan Jones just before Broadbent's retirement 40 years later. It brought an exceptionally congenial and fruitful early collaboration with Peter Ladefoged on speech perception and a lifelong interest in auditory psychophysics and in the subjective and objective measurement of the effects of noise and other stressors on human comfort and performance. Most importantly, it provided applied problems that cued Broadbent's seminal work on auditory multitasking and dichotic listening, which crystallized in his pivotal achievement, his book *Perception and Communication* (Broadbent, 1958).

Modern readers can immediately appreciate that the remarkable impact of this book came partly from a wonderfully lucid style and inspired choice of metaphors that clarified difficult arguments. It is no longer possible to convey its fresh delight for his contemporaries. For all outside a small circle in Cambridge this was the first insight into how an entirely new style of conceptual models, derived loosely from information flow diagrams used by computer scientists, could make sense of exciting new discoveries in momentary and sustained selective attention, short-term memory, arousal, and the effects of stress. The subtext was that the dominant conceptual framework of S–R (stimulus–response) connectionism could not possibly account for these new results. Broadbent's next book, *Behaviour* (Broadbent, 1961) illustrates his recognition of the power of the zeitgeist that *Perception and Communication* had to exorcise. It showed how the behaviorist framework derived from animal learning experiments had become internally inconsistent and that much of the data it had engendered could now be better

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61015-2

interpreted in terms of simple cybernetic models such as those currently being suggested by scientists such as Tony Deutsch and Stuart Sutherland.

In 1958, the year of publication of *Perception and Communication*, Donald Broadbent was appointed director of the APRU and began to attack energetically the hard tasks he inherited, and the even harder ones that he set himself. The funding base of he Unit had to be widened beyond insecure reliance on Royal Navy contracts. Civilian clients, such as the Post Office, the Department of Transport, British Rail, and the Royal Mint were, arduously, brought to recognize practical benefits from human factors research. Part of a self-imposed task of improving public understanding and support in the UK for a misapprehended subject were frequent appearances on radio and television. Effective representation of human experimental psychology through and within the British Association for the Advancement of Science, work with committees and boards of the MRC and the other, newer, Research Councils enlarged academic respect, and secured better funding for psychology in Britain. Similar efforts in the British Psychological Society and the Experimental Psychology Society brought him presidency of both bodies – and membership of even more committees. There was also the day-to-day administration of the rapidly expanding, and increasingly demanding, APRU.

Broadbent always insisted that he could not have continued his personal research without the help of Margaret Gregory, who began to be his collaborator in 1961, and became his wife in 1972. Apart from a diversity of papers on auditory and visual selective attention, decision processes, and stress, Donald Broadbent and Margaret's main work during the 1960s was reinterpretation of data from vigilance tasks in terms of the new metric of Tanner and Swets' signal detection theory. They found that small shifts in operator bias, which could be related neatly to maintenance of arousal and motivation, brought about counterintuitively large changes in patterns of errors. This suggested fresh ways of analyzing the effects on sustained attention of stressors such as fatigue and noise, and of personality variables such as introversion and extraversion. It also led to speculations on distinctions between selective perceptual sensitization for particular signals and preparatory bias for particular responses that became central to his next book, the monumental *Decision and Stress* (Broadbent, 1971), and to much of his later research. However, at the APRU, administrative loads and personal problems became overwhelming. A sabbatical at All Souls College, Oxford allowed personal reassessment and completion of "Decision and Stress," which appeared in 1971. Perhaps election to the Royal Society also brought new confidence in public esteem for his individual contributions, independently of the background successes of the Unit that he had built up. He gave 3 years notice of resignation and in 1974, moved to the Department of Experimental Psychology in Oxford, which was then emerging into a period of preeminence in Britain under the leadership of Larry Weiskrantz. Here, until his retirement in 1991, he at last had his chance to follow Bartlett's advice to work full time on whatever problems he wished.

Decision and Stress immediately achieved widespread respect for its scholarship and its message. Its core is a model for the way information is processed, remembered, and retrieved, expressed metaphorically as a distinction between 'pigeonholing' and 'categorization.' At first sight this seems as potentially helpful as all of Broadbent's other heuristic devices, but generations of students have failed to discover precisely what it means. It seems to contrast control of attention by selective tuning of perceptual sensitivity and by response bias. It is stressed that these functional processes must be guided 'from the top down,' by the complex mental representations that people make of their environments, their momentary and continuing goals, and of the information that they need and the actions that they must perform to achieve these goals, rather than from 'the bottom up' by passive assimilation of sensory input. To do this Broadbent reviewed the entire body of experimental work in applied experimental psychology between 1958 and 1970. Hindsight suggests that the problem was the familiar and inevitable crisis in any rapidly developing science: the style of models that had been so successful in 1958 no longer worked for a new literature and a collection of new experimental results that had become too vast and diverse to be captured by any single guiding metaphor or by models as concise and fruitful as those that *Perception and Communication* was able to draw from the no more than 20 key papers that had been published. The problem of descriptive metaphors that were once new and brilliant being inevitably overwhelmed by new data, cuts as deep in applied cognitive psychology as in all other sciences.

After 1972, Broadbent continued his commentary on the problems of intellectually navigating between finicky debates about the increasingly sterile details of models based on single experimental paradigms, and theoretical frameworks that are so general that it is unclear what they explain or how they can be tested. This was one of the themes of his William James lectures at Harvard, published as *In Defence of Empirical Psychology* (Broadbent, 1973). A background provocation was a fashion, during the 1970s, for rejection of empiricism in favor of 'cognitivist' descriptions. Broadbent's response to the new discipline of 'cognitive psychology' that had been pompously named, but ill-defined, by Ulric Neisser in 1966, had been cautiously tepid. He feared that it might encourage less gifted practitioners to a psychology based on pseudo-philosophical speculation about phenomenology rather than on empirical evidence. This motivated an expression of concern at these trends in British psychology in a paper "In Defence of Empirical psychology" (Broadbent, 1970) published in the *Bulletin of the British Psychological Society*. Broadbent detested academic affectation, particularly grandiloquent posturing to win the generous hearts of students who had not yet been given the critical apparatus necessary to distinguish efflorescing cults of personality from the necessities of methodological rigor and hard-won information. He saw a threat to civilized values when, as he said, "If one doesn't argue from evidence it must come to bludgeons." Perhaps much of his distaste came from what he called his puritanical streak, which took him directly athwart the spirit of the 1970s: "I decided then, and still believe, that self-realisation and the development of personal experience are neither dignified nor respectable goals in life, that most of the world lives within extremely tight economic margins and that positions of privilege (such as the conduct of psychological research), demand obligations in return."

During the later 1970s and the 1980s he commented shrewdly on early connectionist models by McClelland and Rumelhart, on parallels between human experts and expert computer systems, and became concerned with levels, hierarchies, and the locus of control, and the effects of emotional states and personality traits on selective attention and decision-making. He warmed to the strong neuroscience bias that Larry Weiskrantz had brought to the Oxford University Department. He proposed a 'Maltese Cross' model to describe interactions between modality-based memory subsystems and their mutual control to achieve selective attention. His empirical research continued on a remarkable breadth of topics: how the emotional valence of words affects the speed with which they can be recognized; more general problems of word perception and visual perceptual selectivity under stress and distraction and, with Margaret Broadbent and Sue Gathercole, on the processing of rapid strings of successive visual stimuli, and with other distinguished collaborators on grouping effects in short-term memory.

Broadbent never lost his determination to apply psychology to economically and socially useful ends, and to enrich theory by studying complex real-life tasks rather than artificially simple experimental paradigms. With Diane Berry he investigated how managers develop and use mental representations of the systems that they try to control, providing empirical evidence that their decisions are affected strongly by assumptions, biases, and even by computational procedures that they do not articulate, and of which they may even remain unaware. Parallel work on errors and lapses took place in hospital wards and on automobile production lines, in collaboration with his student Peter Cooper, and with Dennis Gath of the Oxford University Department of Psychiatry. It is a pity that this work has gained far less attention than it deserves, because it teaches precisely those lessons of empirical methodology and acceptance of social responsibility that he most wished to pass on.

Broadbent felt that his self-termed 'puritanical streak' discomforted his younger colleagues, but this was not quite the issue. He could not endure gladly the company of people whom he took to be insincere, or perverse, in their determination to avoid recognition of logical weaknesses in their positions, but he was always as fair and generous to them as he could force himself to be. Any discomfort he provoked did not come from his humane responses but from glimpses of the considerable effort that they sometimes cost him. His intellectual acuity was often intimidating, as was his occasional looming impatience with remarks or behavior that he interpreted as histrionic or unkind. His genuine shyness was disconcerting in one so obviously, and exceedingly, clever and eminent, and sometimes compounded problems of communication, but his underlying kindliness was unmistakable, totally reliable, and amply assuaged occasional unease. He was frugal with praise, perhaps because he was suspicious of merely verbal gestures, but he was endlessly generous and sensitively proactive with practical help. It is excellent that he retired amply convinced of the intellectual esteem of his colleagues and students, but sad that he remained unaware that he had also earned far more affection than he ever realized.

Donald Broadbent's lifetime research legacy is documented in his 247 publications and four books. His death, distressingly soon after his retirement, deprived his family and friends of emotional and intellectual comfort and support, and curtailed further sharp insights on how the intellectual history of the subject of psychology may determine its future.

Broadcasting: Regulation

Eli Skogerbø, University of Oslo, Oslo, Norway

Abstract

By broadcasting regulation, we refer to political decisions and legal and economic instruments by which broadcasting activities, mainly radio and television services directed at a mass audience, are governed. A main distinction between regulatory systems can be drawn between democratic and authoritarian states, another between commercial and public broadcasting. With digitization, convergence, and globalization, the borders between broadcasting and other communications have become increasingly blurred, but the systems have retained their main characteristics.

By broadcasting regulation, we refer to political decisions and legal and economic instruments by which broadcasting activities, mainly radio and television (TV) services directed at a mass audience, are governed. These instruments include laws, rules, statutes, concessions, licenses, and traditions, as well as international law, conventions, directives, and policy making. All these instruments make up the legal, economic, political, and social frameworks within which broadcasting activities are carried out. Naturally, the regulation of broadcasting varies in time and space. First and foremost, broadcasting regulations have varied considerably between countries, as they historically reflected national, political, cultural, social, and economic conditions. Historically, one of the most important structural conditions that led to regulation of broadcasting worldwide was scarcity of resources. Scarcity was technological as the amount of radio frequencies that carried transmission of radio and later TV was limited. In some countries, e.g., the United States, the first years of radio were characterized by chaos in the ether, i.e., by radio stations using the same frequencies and interfering and destroying each other's broadcasts. This situation called for regulations. Scarcity also referred to economic resources as broadcasting soon became a costly industry that in some countries attracted major business interests that had the capacity to monopolize the airwaves. In other countries, lack of capital led to increased state intervention. Both spurred regulations, although with different objectives and effects.

Types of Regulatory Practices – Major Distinctions

There are several ways of typologizing the way broadcasting is regulated but the general rule is that the type of political system that a state has has a fundamental bearing on the way it regulates the media. Accordingly, the first main distinction between regulatory systems can be drawn between democratic and authoritarian states. Another main distinction can be drawn between states that historically have regulated broadcasting as an industry, a commercial market, and those that have regulated broadcasting as a public service such as in the European welfare states where broadcasting historically has been regarded a culture service and regulated in the public interest.

Authoritarian and Democratic Regimes

Broadcasting and all other media will be regulated fundamentally differently with regard to freedom of the media and freedom of expression in authoritarian as opposed to democratic states. Concerning ownership and market behavior, there may not necessarily be large differences. In democratic countries, the media are guaranteed a high degree of autonomy, editorial freedom, and freedom from censorship, persecution, and sanctions. Authoritarian states generally have repressive politics toward the media: either the media are treated as instruments for the incumbent regimes (e.g., the former Soviet Union, contemporary North Korea) or they are censored or placed under laws that to larger or lesser degree restrict freedom to criticize the incumbent political leadership (e.g., Zimbabwe, Uganda). Restrictions on media freedom may take many forms in repressive regimes and may vary from total censorship to no censorship but with heavy fining or penalties for those voicing critical views as countries classified as authoritarian may be repressive to varying degrees. Many states tolerate some degree of media freedom, whereas others exercise heavy censorship on more or less all media outlets. There is not always correspondence between legislation and media freedom: Many countries formally adhere to media freedom and freedom of expression for citizens, but still media outlets are closed down and persecuted and journalists are subject to harassment, persecution, and killings when they publish critical articles about governments, corruption, organized crime, and the like.

Neither is the distinction between authoritarian and democratic systems coincidental with the degree of state intervention in the broadcasting or media sectors. Here, too, there is a fundamental difference between authoritarian and democratic states. The media in authoritarian states may be controlled by state ownership or takeovers, as well as by strict regulation, whereas in democracies, state ownership of broadcasters have been accompanied by an ethos of distance between authorities and media institutions, freedom of expression, and editorial freedom. To illustrate, there are many examples around the world of state-owned or government-regulated public service broadcasting institutions that have or have had a national monopoly and that simultaneously have enjoyed a high degree of editorial freedom. In the Nordic and North European countries, for instance, broadcasting institutions have been wholly or partly owned by the state, but the

relationship between the institutions and the state have been distant, following the principle of 'arms' length' between the state and the media, and similar if not identical policies were followed in the United Kingdom toward British Broadcasting Corporation (BBC) and in post-World War II Japan concerning the public broadcaster NHK. To the contrary, there are also examples of countries where privately owned and market-driven broadcasting institutions have been heavily censored and worked as instruments of authoritarian governments, such as was the case with Brazilian Globo during the military government in the 1960s.

The developments of the Internet, mobile communications, and smartphones with both video and audio playing and recording facilities, and newcomers such as the social media (e.g., Facebook, YouTube, Twitter) have in the past decades made it harder for authoritarian governments to suppress and restrain media freedom. What has been termed the Arab Spring, the revolutionary uprising in the Arab World, most notably Tunisia, Libya, and Egypt, in the course of 2011 and 2012, was by some commentators described as made possible by the social media. Although the media did not cause political upheaval, such examples serve to show that the increased access to mobile communications and many different media outlets facilitate and diversify political communication. The uprisings did not everywhere lead to fast throw-overs of authoritarian regimes and the media have remained strictly controlled in several Arab countries, thereby confirming the tight relationship between political systems and media regulation.

Within democracies, two models of broadcasting regulation have historically been clearly distinguished: the commercial and the public service broadcasting model. They have their roots in different parts of the world and developed out of the societies in which they were set up.

Commercial Broadcasting Regulation

The commercial broadcasting model, regulating of broadcasting as a competitive industry, has its deepest roots in the United States where a distinct broadcasting policy was never formulated. Here, the main objectives of broadcasting regulation were to avoid market failure such as 'chaos in the ether,' monopolization of ownership, and secure access to the airwaves for different opinions, interests, and groups. In the United States, the Communications Act of 1934 for decades was the backbone of broadcasting regulations. It set up the regime that was in power until the late 1990s, and more or less defined the framework within which the American media and broadcasting industry was to develop. Broadcasters were regulated according to dominance in the market by the restrictions on ownership in terms of how many radio and TV stations could be owned by one company or individual and by entry regulations that foreclosed the networks from dominating program production and that divided broadcasting and communications into separate markets. The basic principles remained until the Communications Act of 1996 removed most of the entry barriers between different markets and lifted or relaxed ownership restrictions on radio and TV stations. In effect, these changes were aimed at opening and establishing one communications market, taking into account that the changes in information technologies had undermined the rationale for implementing different regulations for, e.g., broadcasting and telecommunications. In 2014, more than a decade after the lifting of these restrictions, however, the communications markets remain rather separate, although a number of multimedia services are developed in the intersection between them.

Some variant of the market regulation model was adopted in other countries too. In Latin America, the commercial model was adopted in most countries, and in some respects, these countries placed few restrictions on the broadcasters. In Brazil and Mexico, for instance, the privately owned and funded Globo and Televisa, the dominant broadcasters in the two countries, respectively, were allowed to monopolize their national markets in the second half of the twentieth century. The broadcasters benefitted from close alliances with repressive governments in the 1960s and 1970s, and experienced few or no restrictions concerning market expansion, or obligations concerning programming. In regulatory terms, Brazil and Mexico thus can be regarded as historical examples where authoritarian regimes combined strong restrictions on media freedom and freedom of expression with few market restrictions. In Europe, the small state of Luxembourg adopted a regulation that allowed commercial broadcasters, among them well-known RTL, to transmit commercial and popular radio and TV across borders, reaching large and young audiences in many European countries (Paterson and Smith, 1998). Broadcasting regulation in Luxembourg thus represented a quite different tradition than the public service model that was dominant in most Western European countries for decades. The European tradition of vesting the responsibility for production of diverse programs in one or a few public institutions was adverse to the American conception that diversity and pluralism is a product of freedom of expression interpreted as freedom to establish media institutions.

Public Service Broadcasting

In most West European countries, broadcasting was for many decades regulated as a public service, meaning that broadcasting, as other media, have been included among other goods and services that wholly or partly have been provided by means of public policy. Public services are goods provided to the entire population on fairly equal conditions and that should be accessible for all at a relatively low cost. Most European countries centralized their broadcasting services in one or a few institutions either when broadcasting was introduced in the national context or shortly after. Sometimes but not always the broadcasters were wholly or partly state owned, and to begin with, there were few or no distinctions between the state as the regulator of broadcasting markets and the state as actor in the broadcasting sector. Instead, media policy and broadcasting policy were treated as central topics within the larger area of cultural policy, i.e., together with political issues related to maintaining and strengthening national identities, language, history, and culture. As such, in Europe, broadcasting has been and to some extent still is an area considered as a sector for production of cultural goods more than cultural commodities (Lunt and Livingstone, 2011).

The public broadcasting system thus does not refer to one particular type of institution; rather it can be described in

contractual terms as a set of privileges and obligations placed on certain types of service providers. The privileges included exclusive licenses to broadcast and exclusive rights to revenues such as license fees or broadcast advertising. In return, the licensed broadcasters were obliged to provide nationwide coverage and diverse programming that catered to the interests of the entire population (Syvertsen, 2003). This model, as set out by Trine Syvertsen, allowed for national variations in the public service model. The fact that regulating broadcasting as a public service did not mean that identical models were set up in several countries, rather that each country tried to design a system of publicly governed broadcasting within the frames of external constraints and national characteristics, is also a feature that has been emphasized during the 1990s. The model has also proven productive as it incorporates changes in the political developments of the public service systems. In some countries, the public broadcasters held a national monopoly and provided universal coverage and a program menu consisting of enlightenment, education, and entertainment that should appeal to different social and cultural groups. In some countries, license fees were the sole source of revenue for the public broadcasters; in others they drew their incomes from advertising or collected revenues from both these sources. Public broadcasters were designed to cater to a diverse number of national interests (management of scarce resources, security, education, nation-building, news) as they were set up in many European countries in the 1920s and 1930s.

In Europe, a large number of quite different national systems have historically been subsumed under the concept. Public service broadcasting regulations varied from country to country, reflecting the cultural and political characteristics of different states. The large, publicly owned, and centralized organization, such as the BBC, is often regarded as the 'mother' of all public service broadcasters, and a model later exported all over the world, whereas it also easy to find historical examples of public service broadcasters displaying quite different characteristics, e.g., the Dutch or Finnish systems, where different institutions were granted privileges and obligations on different conditions. The Dutch public service system, for instance, incorporated a number of different broadcasters that had in common that they are affiliated with the traditional social pillars of Dutch society, i.e., the religious and social cleavages that until the 1960s divided Dutch society into a number of strictly separate groups. Each of these groups or pillars established 'broadcasting societies' that were allowed the right to operate their own radio station and, at a later stage, produced programs for TV. These broadcasters had the right to collect license fees, and from 1967, they also had revenues from advertising, allocated according to a complicated system. In 1967, a national broadcaster providing news and sports was established in order to provide independent programming (Nederlandse Omroep Stichting, NOS), too. The allocation of, first, radio frequencies and later 'windows' on the national TV channels to 'broadcasting societies' took care of the needs to cater to different audience segments, whereas NOS provided the audience with common references to the national culture, politics, and society. Over time, the pillarized system disintegrated but the Dutch public service system had by 2012 retained many of its main characteristics (Donders, 2012). The model of public broadcasting has, as the examples above show, been constantly changing and adapted under various internal and external pressures. This means that the content and design of the privileges enjoyed by the public broadcasters and the obligations imposed on them have also changed over time, but not simultaneously. In the United Kingdom, BBC lost its monopoly in the mid-1950s, whereas in neighboring Norway, the NRK retained this privilege until the beginning of the 1990s. After 2000, some countries have abandoned the license fees, whereas others have retained it.

Although there have been many predictions of the demise of public broadcasting, the public service broadcasters have remained more or less intact all over Europe. As the examples above show, the public service broadcasting model has been continuously under pressure for decades, by challenges in the form of increasing competition, convergence, and globalization of markets. Nevertheless, there has been a growth not a decline of public broadcasters throughout the world lately. The model was exported to many African countries as a legacy of colonialism and several African countries too have adopted the public service model more recently. Post-1990, public broadcasting has been a model for the new democracies in Eastern Europe too. The model has in spite of the discourse of continuous crisis, proved viable, tenacious, resilient, and exportable, and it may prove to be so for the foreseeable future (Jakubowicz, 2011; Bardoel and d'Haenens, 2008; Storsul and Syvertsen, 2007).

Convergence, Globalization, and Competition

In recent decades, nevertheless, the borders between broadcasting, telecommunications, print, and online media in terms of technologies and market have increasingly become blurred as a result of digitization and convergence of production and transmission technologies. Broadcasting institutions no longer are restricted to transmitting their services over broadcast networks, they operate a number of online and mobile services as well, such as news Web sites, online radio and TV, streaming services, and mobile applications, only to mention a few. These developments have changed the relationship between broadcasters and their audiences. Audiences now have access to broadcast services over widely different platforms that are internally competitive, and they have also become important producers of and contributors to programs and services. All these factors, combined with internationalization and globalization of the media industry, have challenged traditionally models of broadcasting regulation. Digitization, globalization, and liberalized economic policies have spurred processes of reregulation and liberalization in communications policies all over the world, making the distinctions between interventionist and market systems less obvious. The public service and the commercial model historically could be different systems, whereas over the past decades, hybrid or mixed models have become common in Europe and elsewhere. Canada and Australia early set up mixed systems, Britain introduced its duopoly consisting of the BBC and the independent broadcasters in 1956, and most other European countries followed suit during the 1960s and 1970s. The Scandinavian countries and Belgium were the last countries to introduce nationwide commercial broadcasters in the early 1990s, the so-called

hybrid channels. Hybrid channels were private broadcasters granted the privilege of tapping the national advertising market in return for complying with public service obligations concerning programming and coverage. The group of mixed systems is large, diverse, and increasing, reflecting technological as well as political changes in the broadcasting sector.

In Europe, the opening of markets and equalization of competition that have taken place within the European Union have had important influence over national broadcasting and communications policies. Over the past decades, all member states in the European Union as well as most other countries have opened their broadcasting sectors so that the public broadcasters become one of several broadcasters that the national audiences can choose from. Further, the European Union has decided on a set of regulatory measures of which some are aimed at protecting the public broadcasters (e.g., the Amsterdam protocol 1997) and some are aimed at securing equal competition and a level playing field (the Audiovisual Media Services Directive, the AVMS Directive). By many commentators, the EU provisions are regarded as conducive to imposing commercial broadcasting regulation all over Europe.

Still, in 2014, when the globalization of the media industry has become conspicuous, it is fair to state that regulation of broadcasting to a considerable degree remains within the hands of individual states, although the mixed pressures of technological change, globalization, and market harmonization have added to leveling out some of the differences. This is true even if we consider the attempts of international organizations, such as the European Union and the United Nations, to establish international regulations for media freedom, trade in audiovisual products, and other issues concerning cross border broadcasting. A common and pressing issue for governments is, however, to find ways of meeting new issues and problems raised by converging media, i.e., the fact that the media no longer are confined within one technological platform for distribution and production. Broadcasters not only operate TV and radio channels but also publish Web sites and distribute news and other services on social media and on applications for mobile phones and tablets, and their programs may be viewed on TV screens, mobile media, or on a computer screen. Other media such as the traditional newspapers have become equally multimedial. While most continue to publish a print edition, they also publish online newspapers, Web TV, online services, and more.

Research on Broadcasting Regulations

As a field of systematic research, the politics and regulation of broadcasting have developed gradually from the 1970s onward. Although the broadcasting industry and the broadcasting institutions received much attention from the moment they were established, they were not generally subject to systematic analysis studies until the 1980s. There are several explanations for this. The first and most obvious one is that communication studies in many countries were not established as a separate academic field. To the degree that there existed a research tradition on media policy and politics in general and broadcasting regulation in particular, studies tended to be either descriptive country studies accounting for one specific broadcasting system or they were efforts to typologize regulatory regimes across the world.

One example of early typologies that gained much attention was the book *Four Theories of the Press* by Fred S. Siebert, Wilbur Schramm, and Theodore Peterson. Writing at the peak of the Cold War, they divided the world into two main categories of media regulatory regimes. Their main distinctive criterion was the type of state, democratic or authoritarian. Within each of these categories, they distinguished between two types of media systems. Democratic states could have 'liberal' or 'social responsible' media regulation, broadly referring to countries with commercial media markets and countries with a higher degree of state intervention. Within authoritarian regimes, a Soviet-Communist media system was set up as a specific variant (Siebert et al., 1956). Another, less well-known typology was presented by Raymond Williams. Williams distinguished between authoritarian, commercial, and democratic systems. This was also an effort to set up a universal typology over media regimes, with the exception that Williams argued that fully democratic regimes were nonexistent and needed to be established (Williams, 1968). Both typologies were prescriptive rather than descriptive and did not in any detail describe the conditions under which different regulatory systems developed. In 2004, Daniel Hallin and Paolo Mancini published their modern, already classic, typology of media systems. Unlike their predecessors, they had no global ambitions but limited their classification to Western Europe and North America (Hallin and Mancini, 2004). In their terms, the Polarized Pluralist Model applied to the Southern European countries, France, Portugal, Italy; the Democratic-Corporatist to the North European countries, and the Liberal to the United Kingdom and North America. The models characterize the media systems as a whole, not only broadcasting, and point to some of the main characteristics of media markets and regulatory characteristics of each of these types. The typology is constructed from comparisons of structural and systemic characteristics of media markets, journalism, and media institutions across countries, the authors relying on existing qualitative and quantitative data. It is intended as "a theoretical synthesis and framework for comparative research," providing hypotheses and concepts (Hallin and Mancini, 2004: 16). As such, the typology has been widely discussed in media research and has been criticized for its shortcomings, empirically and conceptually. As the types to a large extent rest on historical and structural data, the critics have been mainly occupied with the conceptual 'fit' of the types and the validity, less with empirical testing (Humphreys, 2012; Herkman, 2009).

The relative stability of national regimes and broadcasting institutions between 1950 and 1970 probably contributed to the lack of studies investigating, comparing, and contrasting national broadcasting systems in order to arrive at more precise models. In spite of the fact that TV in this period replaced radio as the dominant electronic mass medium in most of the Western world, the introduction of the new medium in general did not change the existing regulatory regimes. In countries that had a national monopoly on broadcasting, TV services were opened within the existing institution (e.g., Britain, Scandinavia). In countries that had a commercial system, TV services were provided by the existing actors (the United States), and in authoritarian states, TV was controlled and used as an

instrument for government propaganda in the same way as radio and newspapers.

In research, media politics and regulation had its breakthrough in the 1980s, as the old models came under pressure by driving forces originating in technological as well as political and economic changes. These changes also spurred renewed interest into describing and evaluating the media regulation and media institutions, among them the broadcasters. Increased interest among media researchers for studies of the political and regulatory aspects of the media to some degree replaced the preoccupation with power and influence of media institutions, media corporations, and media content that dominated research in political communication in the preceding periods. One of the outcomes of renewed interest into media regulation was an increase in the number of comparative studies of broadcasting regulation. Research into broadcasting typically had meant country studies, whereas the late 1980s and 1990s saw an upsurge of works that compared and contrasted national systems. These studies put different systems in relief to each other and reconceptualized the characteristics of national systems into general models, such as the coining of the 'public service broadcasting' model as an analytical concept in the early 1990s.

Technological changes, in the 1980s illustrated by the venture of transnational satellite TV and in the 1990s by the breakthrough of digital networks, brought a whole range of new products and services. This created a new situation of 'communicative abundance' Karppinen, 2012 in sharp contrast to 'scarcity,' which was one of the foundations for broadcasting regulation. At the same time, many Western countries saw deep-going political change, in the sense that liberal governments initiated reforms and liberalization of some of the previously protected sectors, such as telecommunications, energy, and infrastructure (i.e., New Zealand, United Kingdom, Norway). Reforms of the public sector (new public management) affected also broadcasting in particular by the breaking up of the remaining broadcasting monopolies. As a direct consequence, media politics and regulations in the last two decades of the twentieth century were not only moved high on the agenda for national policy makers but also discussed in regional and international forums such as the Council of Europe, the European Union, and the World Trade Organization.

Adapting Broadcasting Regulation to the Age of Digitization

The first decade of the twenty-first century has framed broadcasting within a media landscape where the processes of digital change, marketization, and globalization have continued to influence services, institutions, and policy making. Many countries have again undertaken profound revisions of their broadcasting legislation. In the United States, ownership regulation has been radically softened, and broadcasting is no longer as protected toward monopolization as before. In the United Kingdom, the 2003 Communications Act set up an entirely new way of regulating broadcasting and communications markets, implementing a common regulatory agency for broadcasting, telecommunications, and digital services. A large number of states (e.g., Finland, Norway) have either phased out analogue distribution of TV and radio or put up a deadline for the transition to a fully digital distribution.

The study of media politics and regulations is still a relatively young field within communication research. During the 1990s, the number of empirical studies comparing different national broadcasting systems increased markedly. This development signals that there is a methodological reorientation in the field, emphasizing descriptive and explanatory analyses of a few cases at the expense of normative evaluation of universal models. The comparison of national systems yields insights into the conditions that have shaped broadcasting institutions and provides knowledge necessary to understand the current political conflicts on how to regulate broadcasting under new conditions, both nationally and internationally. In media studies, there is a long tradition for adopting an implicit, not explicit, normative (critical or liberal) approach when phenomena are analyzed, which sometimes has created problems of analytical clarity. With the increased focus on comparisons, these problems may be overcome, as normative judgments will have to be made more explicit.

Broaden-and-Build Theory of Positive Emotions

Suzannah F Isgett and Barbara L Fredrickson, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Abstract

The broaden-and-build theory of positive emotions stems from a set of twin hypotheses. First, the broaden hypothesis proposes that positive emotions momentarily expand our perception of the world in ways that facilitate global visual processing, better attentional flexibility, and larger thought–action repertoires. The build hypothesis purports that, over time, these fleeting experiences of expanded awareness that accompany positive emotions such as joy and excitement accumulate over time to facilitate growth of a person's social, cognitive, emotional, and physical resources. Empirical evidence supporting these hypotheses is discussed, as well as the theory's implications for behavior, psychological resilience, social interaction, and health.

Introduction

Emotions permeate the very fiber of our lives, affecting our judgment and behavior, as well as our health and happiness. Despite their importance to our everyday lives, they can be operationally difficult to define. Broadly described, emotions are brief, multisystem responses to the way individuals appraise their current circumstances (Fredrickson, 2013). These responses last for just seconds or minutes, and when natural and healthy, serve adaptive functions. Just as our bodies sense fluctuations in the physical environment and adapt accordingly by regulating our heart rate or hormones, emotions allow our minds to adapt to the surrounding social or physical environment. For example, the emotion of anger prompts us to approach the source of the emotion to resolve or better understand a conflict. Fear signals our body to flee from danger to avoid potential harm.

Positive emotions are a special class of emotions; they are responses to an individual's current beneficial circumstances. For example, joy is a positive emotion that emerges when one's current circumstances present unexpected good fortune. Serenity, sometimes called contentment, arises when one interprets his or her circumstances as utterly cherished, right, or satisfying. Love, the most frequently experienced positive emotion, is felt in the context of a safe interpersonal connection. Other positive emotions, such as gratitude, interest, hope, pride, amusement, inspiration, and awe, spring from different ways of appraising one's circumstances as beneficial in some way. Any event or situation can elicit multiple emotions, both positive and negative, which adds to the richness and depth of the human emotional experience.

Positive emotions, like those mentioned above, also serve adaptive functions, although scientific evidence for their importance – relative to negative emotions – has been slower to accumulate. During the mid-twentieth century, the burgeoning field of psychology was largely studied under the doctrine of behaviorism, in which observable behaviors are only attributable to the environment and not to mental states. Within this methodological and analytical approach, all emotions were largely deemed irrelevant and misleading epiphenomena (Skinner, 1974). Eventually, emotions began to be studied more rigorously as the zeitgeist of psychology shifted once again to include mental states. However, for decades the focus was still on negative emotions – like fear, anger, or disgust – that could be linked to serious societal issues such as violence, social ostracism, or mental illness. In the history of psychology, only recently have positive emotions been rigorously studied.

However, positive emotions differ from other types of positive states. Hedonic pleasure is a positive response to physical sensations such as eating food or having sex that requires no appraisal of meaning. Optimism is an enduring mental attitude that leads people to interpret events and situations as good. It is not in itself a positive emotion, although it does predispose people to experience more positive emotions. Even positive affect or mood, although components within positive emotions, refer more to an unfocused, diffused state of being. Positive emotions, though momentary or fleeting, are unique in that they cause patterns of thought that are flexible, inclusive, creative, and forward-looking (Fredrickson, 2013).

While it is intuitively easy to consider the adaptive functions of negative emotions such as fear, it is less clear as to how positive emotions serve us. One can imagine and even personally relate to how strong negative emotions alter our thoughts and behavior. On the other hand, what does a fleeting moment of serenity do for us? Do positive emotions exist solely to make us feel good, or do they serve another purpose? These questions, among others, are addressed by the broaden-and-build theory of positive emotions.

The broaden-and-build theory synthesizes two hypotheses that encapsulate the beneficial effects of positive emotions on cognition, behavior, as well as both mental and physical health. The first hypothesis – the broaden effect – proposes that positive emotions have momentary effects on cognition and behavior that expand our awareness and repertoire of what we want to do. The second – the build effect – posits that moments of broadened awareness, sparked by positive emotions, accumulate and compound to build people's personal resources, whether social, emotional, or even physical. Moreover, these effects are marked by reciprocal causality, in that many of the resources that positive emotions help to build also increase the odds that people experience positive emotions, leading to an 'upward spiral' of well-being and flourishing mental health (Fredrickson and Joiner, 2002). The empirical evidence for the broaden-and-build effects of positive emotions is explained below, as well as the theory's implications for resilience and health.

Evidence for the Broaden Effect

Global Bias in Global–Local Processing

Although we take in information through our five senses, we do not consistently process it in the same way. In fact, the details of our environment that enter our awareness may differ based on a stimulus's saliency, its relevance to a situation, or even depending on our mental state. Research in cognitive science has shown that we can process stimuli *globally*, by evaluating a stimulus holistically, or *locally*, by attending to the details. In a paradigm first developed by Navon (1977), participants are shown a geometrical figure that possesses both global and local features and are then asked to choose which of two comparison figures is most similar to the target figure. One comparison figure is similar to the target in its global aspects; the other figure, in its local aspects (**Figure 1**). Decisions on this task have been shown to correlate with certain individual differences. A local preference tends to be associated with anxiety and depression, whereas a global tendency is associated with subjective well-being and optimism (Basso et al., 1996).

Positive emotions lend a global preference to the way people process information. In a study by Fredrickson and Branigan (2005), people temporarily induced to feel the positive emotions of amusement or contentment (through video clips) chose the 'global' comparison figure significantly more than people in a neutral condition. Other studies have linked genuine smiles (Duchenne smiles), characterized by engagement of muscles that raise the corners of the mouth and those that raise the cheek near the eye, to global preferences in processing stimuli (Johnson et al., 2010). In line with the global orientation that positive emotions evoke, they appear to literally broaden the scope of what we see. In Wadlinger and Isaacowitz's (2006) study using an eye-tracking apparatus and visual arrays that included central and peripheral images, participants who were induced to feel a positive emotion before the experiment spent more time, relative to the control group, looking at peripheral images and more frequently changed the location of their gaze.

Supporting the notion of broadened visual attention, a functional magnetic resonance imaging study by Schmitz et al. (2009) examined brain activity in people while they experienced positive, negative, or neutral affective states. Specifically, the researchers were interested in how different emotional states influence visual processing. Participants were shown images of faces, which were superimposed on pictures of different houses. When participants were induced to be in a positive emotional state, they exhibited distinct patterns of neural activity in the parahippocampal place area, a brain region associated with processing of scenes or places. The authors concluded that positive states cognitively expand our field of vision, such that we process more peripheral visual information. Thus, positive emotions seem to literally broaden people's visual scope.

Figure 1 Sample global-local items used to test the broaden hypothesis.

Since positivity tends to increase our awareness of global features instead of just the details, people experiencing positive emotions have a temporarily expanded awareness of their surroundings. In addition, this shift in cognition has the potential to increase our semantic access and expand awareness, allowing more open and creative problem solving. Having a broadened scope of awareness may enable us to recognize opportunities more easily, and – colloquially speaking – not miss the forest for the trees.

Attentional Flexibility and Enlarged Thought–Action Repertoires

In addition to expanding awareness, positive emotions can enhance attentional flexibility. The ability to maneuver the direction of our attention with ease is essential for learning, problem solving, and healthy emotional functioning. Not being able to flexibly control attention can lead to rumination about a problem in our lives, or distractibility when focus is necessary. Johnson et al. (2010) used facial electromyography to detect Duchenne smiles in participants given an attentional orienting task, and found that a higher frequency of genuine smiles, after an experimentally induced positive emotion, predicted greater attentional flexibility in the task. Isen et al. (1985) demonstrated that experimentally induced positive affect led to more unusual words produced in a remote associates task, which is often used as an indicator of creative ability. Similarly, Rowe et al. (2007) showed that positive emotions, induced through music, increased the scope of semantic access and visual attention. By broadening our cognitive resources, such as attentional flexibility, positive emotions allow us to more easily access disparate ideas and flexibly direct our focus.

Positive emotions also broaden our repertoires of what we want to *do*. In a study by Fredrickson and Branigan (2005), participants had a larger breadth of action urges – or activities they wanted to do – after viewing video clips that induced positive emotions, whereas clips that induced negative emotions actually narrowed the breadth of action urges relative to neutral states. Although sometimes fleeting, positive emotions put us in a mental state that allows us to see more, think more broadly, and want to do more.

Inclusive Social Thinking

Finally, the broaden effect of positive emotions can be witnessed in the social domain. In everyday life we tend to think of people in terms of social groups: "Is he one of 'them' or one of 'us'?" "Would I consider her to be in my social circle?"

Although social in-groups can help facilitate social bonding and trust, they can also lead to exclusion and prejudice against out-group members. Because positive emotions broaden our scope of awareness, the way we think about social groups becomes more inclusive. For instance, while experiencing positive affect, people form more inclusive positive categorization, such that they are more likely to perceive a person as a member of an in-group rather than an out-group (Dovidio et al., 1998).

Additionally, positive emotions have even shown to soften the boundaries of racial categorization. A robust phenomenon studied in social psychology is the own-race bias in face recognition, in which people are better able to recognize individual faces belonging to members of their own race, relative to other races (Meissner and Brigham, 2001). Because faces are generally processed by their holistic properties as opposed to a collection of features, it is possible that the own-race bias partly emerges from less holistic face processing of cross-race faces (Tanaka et al., 2004). Because positive emotions enhance global processing, Johnson and Fredrickson (2005) sought to test the effect of positive emotions on facial recognition in own-race and cross-race faces. In a sample of Caucasian individuals, participants induced to feel joy showed nearly the same level of accuracy in recognizing black faces as white faces, whereas participants in the fear-induction or neutral condition still displayed the often-observed own-race bias in racial recognition. While the mechanism behind this effect is unclear – whether it is a change in global processing or general formation of more inclusive social categories – this study provides evidence of ways that positive emotions broaden within social domains.

Positive emotions expand the breadth of overall social connection, and in turn people exhibit more perspective-taking and compassion for dissimilar others, such as individuals from another cultural background (Fredrickson, 2013). Waugh and Fredrickson (2006) proposed that because positive emotions elicit greater social inclusiveness, they subsequently produce greater feelings of oneness between people in a new relationship. This was shown in a sample of first-year college students; compared to those who experienced relatively few positive emotions, participants who experienced relatively more positive emotions in daily life reported greater feelings of connectedness with their new roommate. When our social thinking is broadened, we may be less constrained by narrow social categories and therefore better able to recognize others and interact in ways that foster interpersonal connections.

Overall, evidence across multiple domains shows that positive emotions can temporarily broaden our scope visually, cognitively, and socially. When a positive emotion arises – whether it is joy, contentment, amusement, or love – our attention becomes more flexible, and processing becomes more global. Our visual scope is literally expanded, and we feel the urge to do more. Importantly, our social thinking expands as well. Taken as a whole, such broadened awareness appears to enhance people's ability to recognize a variety of opportunities.

Evidence for the Build Effect

Empirical evidence that supports the broaden effect of positive emotions provides the scientific foundation for the build effect, as well as the broaden-and-build theory as a whole. Although inextricably connected, the timescales of the broaden effect and the build effect are different. Broadened awareness happens in the moment; a brief experience of awe, for instance, allows us greater semantic access. However, the build effect happens more gradually, over the long term, as the broaden effects of positive emotions accumulate and compound over time. These micro-moments of positive emotions grow into stable affective dispositions that foster our physical health and render life more satisfying. While the effects are stronger for people with more frequent positive emotions, nearly everyone can harness the long-term benefits of positive emotions. The social, physical, and mental resources that are part of the build effect are typically shown in longitudinal studies, since a one-time laboratory visit cannot capture this long-term cumulative effect of positive emotions. When the broaden-and-build effect takes place, it can initiate an 'upward spiral' of positive well-being, in which positive emotions build enduring and consequential personal resources, such as social support, resilience, or better awareness of one's environment. These resources in turn beget future positive emotions. Empirical evidence for the build effect's impact on psychological, social, and physiological resources is described below.

A field experiment by Fredrickson et al. (2008) provided the first empirical evidence of the build effect, testing how increasing the daily amount of positive emotions can increase cognitive, psychological, and social resources. To experimentally achieve this in a sample of adults, participants were either assigned to take classes in loving-kindness meditation (LKM) or were assigned to a monitoring waitlist control group. Because LKM trains the mind to generate feelings of love and compassion for self and others, it is an effective technique of learning to self-generate positive emotions. The experimental group showed significant increases in their daily reports of positive emotions (**Figure 2**), which predicted subsequent increases in personal resources, including mindfulness, social support, purpose in life, and even fewer physical illness symptoms. In turn, the elevation in personal resources led to increased life satisfaction and lessened depressive symptomatology. Thus, by learning to cultivate more positive emotions, people can build personal resources that improve their lives.

Figure 2 Week-by-week positive emotions by experimental condition. Note: Meditation training centered on loving-kindness meditation. Positive emotions were computed as the mean across all positive states on the mDES, rated on a scale from 0 to 4.

Psychological Resources

Being able to flexibly adjust to the trials and tribulations of life requires substantial psychological resources. People who are depressed tend to show bias toward negative faces, narrowed attention, and have difficulty coping with stressors. Unfortunately, the inability to cope only leads to worse psychological outcomes. Upward spirals can counter these *downward spirals* of narrow-minded thinking and negative emotions. Broad-minded coping, which captures the degree to which people can step back from their current problems and take a big-picture perspective, is predicted to increase over time with levels of positive emotionality (Fredrickson and Joiner, 2002). This reciprocal relationship between broad-minded coping and positive emotions speaks to how positivity builds psychological resources little-by-little over time.

Flourishers are individuals who rate higher than average on mental health and positive emotionality, and, in addition to experiencing bigger boosts from everyday positive emotions, they also show greater gains in resources, which in turn predicts increased levels of flourishing in an upward spiral dynamic (Catalino and Fredrickson, 2011). Luckily, the build effect is not only for those who start out positive and end up more positive. In a study exploring the benefits of mindfulness training (Garland et al., 2011), there was a reciprocal relationship found among positive reappraisal, trait mindfulness, and emotional well-being. Thus, if individuals learn how to self-generate positive emotions, as through mind-training techniques, an increase in those psychological resources may ensue.

Social Resources

People who express and experience more positive emotions also report being more socially connected. In a longitudinal study in secondary school teachers, positive emotions at work were reciprocally related to an index of social support. Positive coping also has a reciprocal relationship with an interpersonal trust (for a review, see Fredrickson, 2013).

Examining the longer-term effects of positive emotions, Kok et al. (2013) assessed how learning to self-generate positive emotions, via LKM, had effects on perceptions of social connectedness. A sample of community adults was either assigned to learn LKM for 6 weeks or serve in a monitoring waitlist control. Over the 9 weeks of the study, participants reported their daily positive emotions, as well as the degree of social connection they felt. Relative to the waitlist control group, participants in the LKM condition showed significant improvements in the amount of daily positive emotions they experienced, which in turn predicted greater social connectedness. The broaden effect of positive emotions enables people to feel more socially embedded within their community, as indexed by perceptions of social connectedness (Fredrickson, 2013).

Physiological Resources

Beyond self-report measures of positivity and subjective well-being, physiological data also support the build effect of positive emotions. Kok and Fredrickson (2010) explored the relationship between positive emotionality and a physical resource, cardiac vagal tone (VT). VT is the subtle functional arrhythmia in heart rate associated with respiration, marked by a decrease in heart rate during exhalation relative to inhalation (Porges, 2007). This physiological measure can be considered an important biological resource because higher VT (as measured by heart-rate variability or respiratory sinus arrhythmia) is generally associated with a range of mental and physical health outcomes: socioemotional well-being, better emotional and attentional regulation, as well as lowered risk for cardiovascular disease, diabetes, and obesity (Fredrickson, 2013; Porges, 2007). Like other personal resources, Kok and Fredrickson (2010) found that increases in VT were reciprocally related to increases in positive emotion.

However, it is important to determine whether or not changes in VT can be experimentally manipulated by using a positive intervention. Because of its ability to attune the mind to feelings of love and social connection, LKM training – as described earlier – can be used as a type of positive intervention. Kok et al. (in press) linked this type of positive intervention to changes in VT. By teaching people how to self-generate positive emotions through LKM, positive emotions increased over the duration of the study, and VT moderated this effect. That is, people higher in VT showed greater increases in positive emotions. Importantly, people in the LKM group showed larger increases in VT. This study experimentally linked how daily boosts of positive emotions can have effects on not only subjective well-being, but also objective markers of health as well.

Applications

Understanding how positive states initiate a series of cognitive and behavioral effects can lead to better approaches to improving human well-being in both clinical and nonclinical settings. In this section, the implications of the broaden-and-build theory for personal resilience and health will be explored.

Apart from the psychological and health benefits of the intertwined broaden-and-build effects, experiencing positive emotions may have implications for daily life and workplace environments. For instance, broadened visual awareness sparked by positive emotions has been linked to better steering performance in a driving simulator (Trick et al., 2012). Because positive emotions increase attentional flexibility relative to negative emotions or neutral states, they may aid with better task switching, especially when encountering novel information (Wang and Guo, 2008). In the world where both personal and work-related information are constantly updating and evolving, being able to encounter new information with attentional flexibility might aid in the fast-paced structure of the digital age.

The broaden-and-build effects of positive emotions also have special relevance in the workplace, where efficiency and flexibility can lead to a more productive work environment. Increasing the daily amount of positive emotions, which momentarily alter cognition in beneficial ways, might over time increase our personal resources in organizational contexts. In addition, some work tasks require creativity, integration of information, and seeing the big picture. In both cases, positive

states not only feel good, but may also foster more productivity as a by-product of these broaden-and-build effects.

Implications for Resilience

Resilience can be defined as one's ability to cope and 'bounce back' from life stressors, such as the death of a loved one, loss of a job, or a national crisis like the attacks on 11 September 2001. While some individuals are able to manage their negative emotions and eventually get back on track, others struggle to regain psychological well-being and are pulled into a downward spiral of negative emotions which can even slide into clinically significant emotional disorders. However, the broaden-and-build effects of positive emotions can buffer us, helping us climb over the wall of stress and hardship, back to a normal and healthier life.

The heart of resilience can be partly traced to the *undo effect* that positive emotions have on negative states. Biologically, positive emotions undo the cardiovascular effects of a negative emotion. In a study conducted by Fredrickson et al. (2000), anxiety-related cardiovascular reactivity was induced in a classic stress task, which instructed participants to prepare a speech to be recorded and evaluated by peers. However, they were also told that if a video clip began playing, they no longer needed to give the speech. The clips presented were intended to induce contentment, amusement, sadness, or a neutral state; speed of cardiovascular recovery was measured by the length of time it took for the person to return to his or her baseline cardiovascular levels. Viewing a positive video clip (i.e., contentment or amusement) quickened cardiovascular recovery, relative to sad or neutral clips. The authors demonstrated that positive emotions can provide your body and mind with the psychological resources it needs to recover from stressful events.

While the Fredrickson et al. (2000) study shows that positive emotions allow better recovery from a stressful task, how do these effects of positive emotions translate to the real world? Cohn et al. (2009) examined the relationship between emotions, life satisfaction, and resilience in a sample of college students. For 1 month, participants reported their daily emotions, and they evaluated their life satisfaction and ego resilience – the ability to flexibly respond to challenging or shifting circumstances – once before and once after the month of daily reporting. The authors found that, even though resilience was related to both life satisfaction and daily positive emotions, only positive emotions – not life satisfaction – predicted an increase in resilience over 1 month. Intriguingly, daily negative emotions did not significantly influence the benefits of positive emotions. Therefore, experiencing frequent positive emotions helps people lead more satisfying lives by generating greater resilience to the hardships and challenges we all face.

Additionally, evidence from brain scan studies shows that individuals with resilient personality styles exhibit less enduring neural activity to negative cues in the anterior medial prefrontal cortex and posterior cingulate cortex, a brain regions broadly associated with self-referential processing and rumination (Waugh et al., 2010). This study suggests that resilient people focus less on worrying about what is to come and take a more open-minded awareness approach. As mentioned earlier, 'broad-minded coping' is the ability to step back and evaluate a situation more broadly; this form of resilience has a reciprocal building effect with positive states.

However, resilience is not a completely static, individual trait. People can work on improving their resilience by cultivating more positive emotions. In another study by Tugade and Fredrickson (2004) in which participants were instructed to give a speech (a stress inducer), individuals without resilient personality styles who were randomly assigned to reframe the task as a positive, exciting challenge showed the quick physiological recovery characteristic of their more resilient peers. Additionally, as described above, a study using LKM to teach people how to self-generate emotions led to boosts in environmental mastery, which is an important component of resilience (Fredrickson et al., 2008).

Implications for Health

When we think of healthy behavior, we typically imagine eating fruits and vegetables, exercising, or refraining from smoking. While these behaviors are crucial to health, all of them focus on the body. After all, it is in our bodies that cancer, heart attacks, or strokes occur. However, these ordinary healthy behaviors do not address how a healthy mind can nourish a healthy body. At first blush, how we process information or feel about our relationships seems to be unrelated to these salient diseases. However, evidence for the broaden-and-build theory shows that positive emotions do not simply feel good, but also affect our physiological resources, such as cardiac VT.

This novel line of research is just the tip of the iceberg. The way we interact with others and our surroundings may influence more in our bodies than VT. Our cells constantly respond to signals from our body and communicate with one another. By regulating gene expression, cells are able to adapt to our ever-changing environment. The genes in our cells' DNA can tell our bodies to make more or less of certain proteins in order to grow, fight infection, or handle an injury, to name a few functions. New research is showing that our social environment can affect gene expression as well. A study by Cole et al. (2007) compared lonely individuals to nonlonely controls, and found a dramatic difference in their gene-expression profiles. In white blood cells – cells that are integral to our immune system – genes that promote inflammation were overexpressed in lonely individuals. Chronic inflammation can initiate a cascade of negative health effects, including an increased risk for cardiovascular disease, Alzheimer's, and rheumatoid arthritis. Therefore, being able to make social connections and feel social support has implications for health. As we have seen, when people initiate an upward spiral of positive emotions, they are more likely to make positive and meaningful connections with others. The broaden-and-build effect of positive emotions may thus enable us to forge meaningful social connections, which in turn may help keep chronic inflammation at bay.

Since the dawn of psychology, the functional understanding of positive emotions has come a long way. Despite being lighter and more fleeting than negative emotions, positive emotions are not just expendable pleasantries. The broaden-and-build theory of positive emotions explains that short-term changes in cognition and behavior elicited by positive emotions can, over time, facilitate people's ability to build

social, psychological, and behavioral resources. Newer lines of research will explore how the broaden-and-build effect influences health and well-being by integrating other areas of science, including brain imaging, immunology, genetics, and medicine.

Brokers and Brokerage, Anthropology of

Johan Lindquist, Stockholm University, Stockholm, Sweden

Abstract

This article deals with the ebb and flow of interest in the broker in anthropology since the 1950s. It attempts to situate this interest in relation to the changing world that anthropology has been concerned with, and in the context of shifting theoretical perspectives within the discipline. Beginning with the era of decolonization and the rise of the new nation-states, it tracks the position of the broker in relation to trends within political and economic anthropology, before pointing toward current concerns in anthropology.

Introduction

The broker is a classic figure in the anthropological literature, particularly with regard to the study of low-level political and economic relationships. It is important to note, however, that there has been an ebb and flow of interest in the broker and brokerage in anthropology. While appearing as a critical figure for anthropology in the context of decolonization and modernization theory in the 1950s and 1960s, and later with the rise of transactionalism, the broker largely vanished from view in the late 1970s before reemerging in the wake of current engagements with neoliberalism. The moral ambiguity of the broker as an individual who crosses social boundaries and whose motives and loyalties are questioned gained increasing force in this process. This article attends to this history, which illuminates some changing concerns in the discipline since the middle of the twentieth century, primarily in the United Kingdom and the United States. But first a statement should be made about definitions. In this article, the broker is a specific type of middleman, mediator, or intermediary. Most generally, the broker is a human actor who gains something from the mediation of valued resources that he or she does not directly control, which shall be distinguished from a patron who controls valued resources, and a go-between or a messenger, who does not affect the transaction. As shall become clear, these ideal-type distinctions are difficult to sustain in the face of a changing empirical reality and innovations in anthropological theory, particularly the concern with mediation, but will serve as a placeholder to attend to the history of the concept.

Historical Trajectories

Even if one can find essays that deal explicitly with middlemen in the anthropological canon, significant anthropological interest in brokers and brokerage does not emerge until the postcolonial era during the 1950s and 1960s, as a growing concern with social change challenged the largely ahistorical perspectives of functionalism and structural-functionalism. This was first made evident through studies that considered the modern village chief or head in Africa as a broker between overlapping fields of African and European political authority, particularly in the context of the Manchester school's focus on situational analysis (Gluckman et al., 1949; but see also Fallers, 1955). Redfield's (1956) concern with the relationship between parts and wholes, between little and great traditions in complex societies, also led to an interest in what he called "hinge groups." There was rarely, however, an explicit attempt to engage in a general cross-cultural or conceptual discussion concerning brokers.

In contrast, classic articles by Eric Wolf (1956) and Clifford Geertz (1960) explicitly developed the idea of the cultural broker as a way to describe shifting forms of political authority and the transforming relationship between village and metropole following decolonization in Mexico and Indonesia, respectively. The work of F.G. Bailey should also be noted, as he clearly identified brokers as 'agents of social change' (1963: p. 101) that allowed for the integration of villages into a wider society in Orissa in India. Generally speaking, these studies attempted to historicize the development of new forms of political relationships through the figure of the broker, particularly in relation to the rise of the new nation-states.

While sociologists for decades had been concerned with the 'marginal man' as a personality type that developed through migration and intercultural relations (Parks, 1928), in anthropology the cultural broker – generally an insider – appeared as a starting point for considering social change more broadly (Press, 1969). In this historical era, Wolf defined brokers as "groups of people who mediate between community-oriented groups in communities and nation-oriented groups which operate through national institutions" (Wolf, 1956: p. 1075). These brokers were 'Janus-like,' turned in two directions at once, and came to "stand guard over the crucial junctures or synapses of relationships which connect the local system to the larger whole" (Wolf, 1956: pp. 1075–1076).

Particular types of individuals – often multilingual and comfortable in multiple settings – emerged as ethnographic exemplars. The African chief has been mentioned, the traditional healer engaging with Western medicine another, but most well known is perhaps the *kijaji*, the Javanese Muslim leader described by Geertz (1960), whose local legitimacy was based on experiences in, and relationships with, the center of the Islamic world, Mecca. With the rise of the Indonesian nation-state, the *kijaji* was drawn into new forms of translocal relations. As Geertz phrased it, while before he was a "scholar, curer, and mystic teacher, he is now a politician," albeit "an amateur" one (1960: p. 247). For both Geertz and Wolf, a new form of ethnographic attention emerged that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12178-6

was concerned with understanding complex systems and the relations between different levels of sociocultural integration. There were explicit disciplinary concerns as well. For Geertz, the focus on the broker was an attempt to find a space between the predominance of community-based studies in anthropology and political science's concern with elites.

The rise of modernization theory during the 1960s positioned the new nations within a developmental framework that considered the broker as a necessary but temporary actor that would disappear with the rise of new rational organizational forms. In the wake of Geertz and Wolf, there were attempts to develop and circumscribe the broker conceptually along these lines. Sydel Silverman, following Wolf, highlighted two criteria: first, 'critical functions' that are of 'direct importance to the basic structures of either or both systems,' and, second, 'exclusivity,' meaning that the links between two systems were monopolized by particular types of individuals (1965: p. 173). In her historical account of Central Italy, Silverman showed how certain patrons came to dominate a wide range of mediating functions between the rural community and the national system, but that after World War II many of these functions were taken over by the state, as the expansion of literacy and education allowed for locals to engage directly with bureaucracy. As such, 'critical junctures' were no longer guarded by one group. In Silverman's account, there is thus a historical relationship between the position of the patron and the broker, as the former takes on the role of the latter during a certain period. Deep-seated relations of inequality – not only based on control of economic resources and familial relations of debt, but also on access to education and the ability to engage with the state – thus formed the basis for new brokerage opportunities. In this context, and in line with modernization theory, the hypothesis was that the broker emerged in an early stage of the development of the nation-state, only to later become unnecessary with the process of integration of local and national levels of society.

The rise of transactionalism – a theoretical position first advanced by Fredrik Barth – focused on the strategic actions of individuals in contexts of social constraint. It was therefore not surprising that leading proponents such as F.G. Bailey, Robert Paine, and Jeremy Boissevain turned their attention to brokerage. In keeping with the methodological individualism of transactionalism, Bailey and Paine attempted to move beyond a model of brokerage based on inequality, such as that outlined by Silverman, to one that considered the nature of the transaction as a starting point. Bailey's *Strategems and Spoils* broadened the discussion considerably by understanding brokers as bridging a gap in communication in a 'situation of encapsulation' (1969: p. 167). In *Patrons and Brokers in the East Arctic* (1971), Robert Paine and his collaborators were, on the one hand, concerned with the Canadian government's expansion into the Arctic, and its effect on indigenous groups, and the role of brokers in this process. On the other hand, Paine attempted to develop a theory of patronage and brokerage that focused on roles rather than statuses based on inequality. He argued that roles were situational and that brokerage should be understood as the regulation of the circulation of values. Boissevain, in turn, identified the broker as "a professional manipulator of people and information who brings about communication for a profit" (1974: p. 148). He argued that centrality of location in networks, time to deal with social relations, and control over first-order resources were all critical in becoming a successful broker (pp. 154ff). The broker's capital lay in the communication channels he controlled, while his credit was what others believed his capital to be (p. 159).

Transactionalists' focus on communication shifted attention more directly toward the formal elements of brokerage as well as the figure of the entrepreneur, thus attending more to economic relations. This was perhaps unsurprising with the rise of rural capitalism in the areas in which anthropologists were concerned. Boissevain's claim that 'brokerage is business' (1974: p. 158) stated this most clearly. But transactionalism's concern with formal relationships also allowed for the potential of bringing the economic and the political into a common frame, thus highlighting the entrepreneurial aspects of politics rather than stable relationships. While the African headman had often been considered a victim of tensions between different groups, the strategic actions of the transactionalist broker highlighted a particular problem, namely that the broker is not able to justify his actions in normative terms. If manipulation rather than the resolution of conflict was at the center of the broker's craft, it was not surprising that he was often despised and considered dishonest. More generally, this pointed toward issues that became increasingly important as anthropologists shifted their attention away from villages toward complex societies, namely issues of trust and interpersonal relations across sociocultural borders.

The Death of the Broker

By the late 1970s, however, the broker had begun to disappear as a focus of concern for anthropology. The question of power had from the beginning been at the heart of well-known debates between transactionalists and Marxists. Even sympathetic critics such as Cohen and Comaroff claimed that although it was important to distinguish the broker from patron, the broker role embodied the essential attribute of power: "the capacity to construct and purvey meanings concerning a variety of relationships and interactions" (1976: p. 89). More importantly, they claimed that political relationships were often based on the creation or mediation of boundaries of meaning rather than transactions within coherent systems of meaning, a point that illuminates contemporary discussions in anthropology and a more sophisticated understanding of the workings of power.

Deborah James (2011) understands the disappearance of the broker in relation to what Jonathan Spencer (2007, Chapter 1) calls the 'strange death of political anthropology,' in which the analysis of local-level politics ran into a 'dead end' with the rise of structuralist (particularly Marxist) models of political analysis and a broad-based understanding of the postcolonial state as the primary site of power and domination in the Third World. There was perhaps also a more subtle shift of attention from the concern with particular persons, such as patrons and brokers, to particular situations that allowed for new forms of relations and brokerage (Vincent, 1978: p. 186). Arguably, however, a series of further trends reinforced the waning interest in the broker. As post-structuralism emerged

with full force during the 1990s, the focus was broadly placed on how power productively disciplined and shaped individual subjectivities, as questions concerning agency were effectively sidelined. In this world, the local-level broker appeared increasingly insignificant in both empirical and analytical terms. In the meantime, with the reflexive critique of anthropology that emerged primarily in the United States during the 1980s, the broker arguably lost relevance precisely because of the crisis of cultural holism, which came to complicate the question of brokerage and how it might be conceptualized. As hybridity came to replace identity, the cultural forms of encapsulation that had formed the basis for an analysis of brokerage were effectively critiqued and disbanded. Finally, during the same period, a technologically centered concern with mediation, primarily in the wake of Benedict Anderson's seminal *Imagined Communities* (1983), came to dominate scholarly debate, as an anthropology of media gained ground (Boyer, 2012). The question of the relationship between mediation and brokerage is one that will be further discussed at the end of this article.

It is worth noting contrary developments within the discipline of history. Richard White's (1991) influential *The Middle Ground: Indians, Empires, and Republics in the Great Lakes Region, 1650–1815* offered a nuanced understanding of relationships between settlers and Native Americans through a focus on brokers. Interestingly, White begins his book with an epigraph from the historian of anthropology, James Clifford, concerning the ongoing critique of the culture concept, thus offering a perspective on the American frontier that moved beyond the 'billiard ball' theory of cultural relations toward one highlighting struggles for accommodation and common meaning. More recently, historians influenced by or trained in anthropology have considered brokers as a starting point for considering imperial governance. Rothman (2011), in her study of brokers in sixteenth-century Venice, successfully combines anthropology and history by illustrating how brokers licensed by the Venetian state did not merely mediate between different categories of actors – that is, 'Venetians' and 'Turks' – but were in fact active in producing the categories of identity themselves by various means and arrangements.

The Return of the Broker

In the past decade, there has arguably been a renewed concern with the broker in anthropology. Transformations in the global economy since the collapse of Bretton Woods and ensuing neoliberal reform have increasingly problematized state-centered models of power and sovereignty and pushed for a reconceptualization of the relationship between state and market. It is in this context that we can note a great potential for the return of the broker in ethnographic terms as an actor that emerges and becomes positioned along these fault lines (James, 2011). Furthermore, technological innovations in transportation, communication, and media have created a transnational landscape that has formed the backdrop for anthropology. It has become increasingly clear that the metaphor of transnational flow needs to be specified empirically and that brokers are critical in this process, not only on the local level but also among the transnational elites that have increasingly become a familiar focus for anthropologists. As noted earlier, in the past few decades a broader focus on mediation has largely displaced the concern with brokers. With the rise of digital media and the internet, in particular, mediation has moved to the center of anthropological attention. As science and technology studies has come to replace cultural studies as a primary interlocutor for anthropological theorizing, however, perspectives such as actor–network-theory have led many anthropologists to problematize the distinction between human and nonhuman agency, thus allowing for a renewed discussion concerning the relationship between brokerage and mediation, and of agency, more generally.

In contrast to the fantasies of ideologues who imagine a world of disintermediation characterized by free markets without borders, in the contemporary moment it appears that brokers are proliferating rather than becoming obsolete. In fact, with neoliberal reform and economic and political deregulation, the broker appears as a critical figure, indeed, one might argue, as an ideal anthropological informant. In the global south, James notes as much in relation to transitional settings such as post-apartheid South Africa, where "state, market, and patrimonial/patriarchal-style political authority intersect" (2011: p. 318). She sees the reemergence of brokers who can mediate between these spheres, in her case in the context of land reform. In what follows, I will identify a few other domains in which the broker has emerged as a site of concern.

Current Trajectories

As tourism has become one of the world's largest industries in recent decades, it has also become a key site of interest for anthropologists. In the relationship between 'hosts' and 'guests,' various forms of brokers, most notably the tour guide, have attracted the attention of anthropologists. In the new anthropology of tourism there is, for instance, the recognition that brokers do not mediate between already existing cultures, but are rather active in producing and encapsulating cultural authenticity, and of commodifying and selling these experiences and images. Macdonald's (2006) work on tour guides in a 'difficult heritage' site, the former Nazi Party Rally Grounds in Nuremburg, highlights one productive site in ethnographic terms, in which guides attempt to control interpretation in different ways. But tourism itself is not easily circumscribed, and the rise of volunteer and retiree tourism points to relationships between leisure and labor, and the rise of new zones of contact and brokerage that are capturing the interest of anthropologists. The rapidly expanding global industry for tertiary education should also be noted in this context, as the recruitment of students depends on brokers, many of them former students themselves.

The global rise of nongovernmental organizations (NGOs), particularly in the context of the development aid industry, but also in transnational activism, has led scholars to consider the role of brokers in these processes. Although Olivier de Sardan (2005, Chapter 11) distinguishes between agents who work directly for donors and rent-seeking development brokers, it is perhaps more fruitful to highlight his point that there is an a priori normative distinction – which has limited empirical

support – between grassroots do-gooders and corrupt actors. Of particular interest in the emerging literature on development brokers is *Brokers and Translators* (Mosse and Lewis, 2006), which is an attempt to combine an actor-oriented approach rooted in the Manchester school of anthropology with a Latourian concern with translation in actor–network-theory. Rather than considering brokers as strictly mediating between aid donors and recipients, the authors ask how unpredictable development projects are actually implemented through the translation of interests, concepts, and practices, and how particular forms of meaning are established in this process.

The anthropology of transnational migration has tended to focus on sites of departure or destination. While social networks and diasporic communities have been widely researched, the commercially oriented migrant broker has been vilified since the advent of liberalism, an ethical position that has often been reproduced in the scholarly literature. This discourse is particularly evident in discussions concerning human trafficking in which there is an enduring distinction between 'victim' and 'perpetrator.' However, in the context of Asia and the Middle East, in particular, there is an ongoing turn from undocumented to documented transnational migration, in which the rise of licensed recruitment agencies has been matched by increasing demands for state documentation. In this process, brokers both convince people to become migrants and negotiate paperwork in relation to the state bureaucracy (Lindquist et al., 2012). As in ongoing discussions concerning the rise of NGOs, neoliberalization and the shifting relationship between the state and market are both creating the opportunity for new types of brokers – who engage both with local populations and bureaucracies – while reproducing an a priori ethical discourse. In an important sense, brokerage has been an ethnographic black box in both the development and migration industries, a fact of which anthropologists are increasingly cognizant.

In the examples noted earlier, we see how the moral ambiguity of the broker – as an actor whose primary commitment appears as maximizing individual gain and is therefore deemed untrustworthy – has remained constant across time and space (James, 2011: p. 319). This ethical position is perhaps most evident in the burgeoning work on the transnational market in organ transplants, in which Nancy Scheper-Hughes (2003), in her brand of militant anthropology, names particular brokers in the 'rotten trade.' On the other hand, it is also possible to see how this position has become problematic in ethnographic terms in relation to the earlier discussion. For instance, Lawrence Cohen (2003) speculates about the rise of 'bioethical brokers' who come to control the discourse surrounding organ transplants. These include scholars and policy-makers, who are certainly often sincere in their intentions, but who should nonetheless be considered as epistemic brokers. Cohen's ethnographic focus thus illustrates a broadened anthropological concern that makes evident multiple fields of brokerage across previously disconnected domains.

Another field in which one can note a renewed interest in the broker is in the anthropology of finance, which has shifted attention toward the economic elites that are at the center of the global economy. Cailtin Zaloom (2006), for instance, in her study of trading floors in Chicago's and New York's financial districts, pays close attention to various types of 'economic men' who broker trades, as financial markets have moved from floor-based to electronic trading. From an anthropological perspective, it is clear that the 'global economy' is made up of actors who are engaged in making actual trades and that this should be considered ethnographically. But the importance of technologies and algorithms in finance has also meant that it is within the anthropology of finance, as well as the anthropology of science, that actor–network-theory has been most influential. The attempt to do away with the distinction between human and nonhuman agents has opened up for a more radical understanding of brokerage. In this context, Latour makes a critical distinction between intermediaries and mediators. The intermediary "transports meaning without transformation" while "mediators transform, translate, distort, and modify the meaning or the elements they are supposed to carry" (2005: p. 39). In fact, it is upon this distinction that Latour makes a contrast to other forms of sociology. From the perspective of actor–network-theory, there exist an endless number of mediators, and thereby brokers, who thereby are positioned at the center of analysis and as a starting point for considering various processes of encapsulation and the production of social forms. A recent example of anthropologists using actor–network-theory is the discussion by Bill Maurer et al. (2013) on the rise of the 'mobile money agent' who functions as a kind of 'human ATM' by facilitating monetary transactions for users via mobile phones. As they note, there are ongoing discussions within the mobile money industry concerning whether the agent is an intermediary and mediator, a classic question in anthropology. Rather than focusing attention on the broker, the mobile money agent itself, Maurer and his colleagues use the industry's interest in the agency of the broker as an entry point for considering ongoing discussions about 'agency' and money, once again illustrating how anthropologists are increasingly considering particular kinds of experts as knowledge brokers.

Finally, it is worth noting the anthropology of media. In Boyer's (2012) review of the field, he notes a shift of attention away from media as a form to mediation as a process, which has in part led to an increasing focus on producers (2012: p. 386), thus suggesting that one question for anthropology in the future is precisely the relationship between brokerage and mediation. In this context, the anthropological interest in journalists is notable, as in Ulf Hannerz's (2004) ethnography of foreign correspondents, and in Zeynep Devrim Gürsel's (2012) work on 'image brokers' in news journalism in the era of digital media. In both cases, anthropologists are concerned with how journalists broker news and images in a process of world-making, thus once again showing how in the contemporary era brokers are less – once again borrowing F.G. Bailey's term – encapsulated than engaged in processes of encapsulation.

Final Thoughts: Ebb and Flow

From one perspective, the ebb and flow of interest in the broker can be considered in relation to the changing nature of the state. While former colonies were transformed into nation-states after World War II, since the 1980s neoliberalization has both transformed the state and modes of governance.

It is therefore worth considering if interest in the broker both reflects a crisis of political authority and a mode of anthropological theorizing in the face of such a crisis. But a major difference between the current era and the earlier one is that while previously it was generally clear what the broker was mediating between, the village and the national capital, or, more generally, encapsulated political structures, in the contemporary context of unbounded fieldsites this is not immediately obvious. This is arguably more of a possibility than a constraint as anthropologists are able to avoid the pitfalls of methodological individualism and consider the broker as an ethnographic entry point that illuminates broader contexts and processes from a particular position of mediation. As such, the renewed focus on the broker moves beyond a static conceptualization of the relationship between the 'local,' 'national,' or 'global,' thus understanding scale as emergent in relation to the ethnography at hand and aiming to set things in motion rather than to resolve or put an issue to rest. The problem of how to describe and conceptualize what the broker mediates between is thus primarily ethnographic, as is the more specific question if the broker is better understood as an intermediary or mediator – actors or entities that make a difference or no difference in the transaction, respectively (Latour, 2005).

Abstract

Jerome Bruner is one of the most original and influential psychologists of all time. His work in psychology and cognitive science played a significant role in making the study of mind as both scientific and human. His interest and influence are also not limited to the field of psychology, but have been extended to related fields, most notably, education.

Life and Career

Jerome Bruner is one of the most original and influential figures in the history of psychology. Some of the key concepts and perspectives in today's psychology, cognitive science, and such related disciplines as education and anthropology are inspired by Bruner's work: for example, cognitive science, folk psychology, cultural psychology, and discovery learning. He has written numerous books and articles, and received awards and honorary degrees for his contributions to the understanding of the human mind. In addition to his work in psychology and cognitive science, he is known for his involvement in education, particularly in the curriculum reform movement in the 1960s and the early 1970s.

His work in psychology or cognitive science played a significant role in making the study of mind as both scientific and human. As part of the larger movement in overcoming the narrowly scientific – or scientistic – approach of psychology in the first half of the twentieth century, behaviorism and experimentalism, he liberally borrowed research methods and findings from various disciplines as well as devised ingenious psychological approaches. He also consistently inquired into the nature of the *human* mind – how it works, how it is formed, and how it can be helped to become what it is – from diverse perspectives.

Jerome Seymour Bruner was born on 1 October 1915, to an affluent Jewish family in New York. Except for his love of books, Jerome was not particularly precocious intellectually. Remembering back to his high-school days, he says that he loved French and mathematics, and also sailing with his close friend whom he calls 'water rats,' which gave him the 'first taste of collaboration' (1983b: p. 19).

He received his B.A. (psychology) from Duke University and Ph.D. (psychology) from Harvard. He had worked for a few governmental agencies, including the Foreign Broadcast Intelligence Service and the Office of Public Opinion Research, and engaged in surveys on propaganda and public opinions in the early 1940s before he turned to research and teaching in university. Later, toward the end of the War, he worked in Paris for the Anglo-American Psychological Warfare Division of Supreme Headquarters Allied Expeditionary Force in Europe (PWD-SHAEF). There he engaged in cultural relations and also witnessed the educational reform led by the physicist Paul Langevin. Through these experiences, he made connections with, and learned from, leading figures in various fields. An example of such encounters was his meeting with Robert Oppenheimer.

Since 1945, Bruner has taught at Harvard University, Oxford University, the New School for Social Research, and New York University (NYU) (he is currently University Professor in the School of Law, NYU). Through his expertise as psychologist and his extensive network of intellectuals and policy makers, he has been involved in various professional initiatives including the establishment of the Center for Cognitive Studies at Harvard in 1960. He also served in the Educational Panel of the President's Science Advisory Committee (in the Kennedy and Johnson years), and was involved, albeit indirectly, in the launching of Project Head Start.

For his contributions to the advancement of psychological research and to educational practice, he has been awarded the International Balzan Prize, the American Psychological Association's Award for Distinguished Scientific Contributions, and honorary doctorates from such universities as Yale, Columbia, and Sorbonne.

Bruner's Cognitive and Psychological Theories

Although Bruner is primarily interested in the formation and development of the human mind, the specific foci of his research have changed over the years: perception and thought in the 1940s and the 1950s (*A Study of Thinking*); intuition, invention, and mythology (*On Knowing: Essays for the Left Hand*); cognitive and linguistic development from the 1960s to the early 1970s (*Studies in Cognitive Growth*; *Child's Talk*); the nature of narrative and various forms of cultural activities (*Actual Minds, Possible Worlds*; *Acts of Meaning*; *The Culture of Education*; *Making Stories: Law, Literature, Life*) since the 1980s.

Borrowing from his Oxford colleague Isaiah Berlin's phrase, Bruner describes himself as "a fox rather than a hedgehog, preferring to know many things rather than one big thing" (1983b: p. 8). As a 'fox,' he does not limit his research to the field of psychology narrowly conceived. Instead, in pursuing the formation and operation of our mind, he liberally borrows insights, research findings, and alternative perspectives from various fields. Bruner writes, "I was … an intellectual first and a scientist in support. … I used psychology to pursue matters that existed for me in their own right. Psychology was (and remains) only one way to use mind in behalf of these pursuits" (1983b: p. 77). In return, his works are constantly referenced and taken as a source of inspiration in various other fields.

He also says that he has a strong 'left-handed' part, that is, a less purposeful, more intuitive character (1983b: p. 5). True

to his word, he has caused a few major reform movements in psychology and education. Through a series of research and publications in the latter half of the 1940s and the early 1950s, he and his colleagues (e.g., Postman and Bruner, 1946; Bruner and Goodman, 1947) launched a new approach to psychology called the 'New Look,' which paved the way for the Cognitive Revolution in the late 1950s. 'New Look' psychology and the Cognitive Revolution were revolts against the then-dominant behaviorism that focused exclusively on the correlation of sensory input and behavioral output without regard to the intermediate mental processes, and against forms of experimental psychology that specialized in animal study or decontextualized behavioral study of people in the laboratory. In other words, Bruner and the 'New Look' psychologists thought that behaviorism and experimentalism, by concentrating on the analysis of the input (stimuli) and the output (response) in order to maintain the scientific and objective appearance, lost sight of mind, while they were supposedly pursuing the science of mind. 'New Look' psychology joined forces with emergent innovative research of the late 1940s to the early 1950s in such fields as computer science (or cybernetics) and anthropology and brought about the Cognitive Revolution, restoring the mind as the center of interest. This movement for the revitalization of the study of mind led to the birth of cognitive science in the 1950s.

The term *cognition* means mental operations such as perception, thought, and memory, particularly of humans. We now tend to use *cognitive science* or *cognitive sciences*, instead of psychology, to imply that psychology alone, let alone the narrowly scientific approach of behaviorism, can enable us to understand the nature and development of our mind sufficiently. Thus, cognitive science is an interdisciplinary approach to the understanding of the human mind and explores what makes our mind work, including language, conceptual systems, cultural foundations of mental operations, whose scopes go well beyond the traditional field of psychology.

In the 1980s, however, Bruner became disenchanted with the Cognitive Revolution, because he felt that the movement lost the initial impetus that tried to restore the mind in the science of mind. He writes:

> The [cognitive] revolution was intended to bring 'mind' back into the human sciences after a long cold winter of objectivism … [But] that revolution has now been diverted into issues that are marginal to the impulse that brought it into being. Indeed, it has been technicalized in a manner that even undermines that original impulse. This is not to say that it has failed: far from it, for cognitive science must surely be among the leading growth shares on the academic bourse. It may rather be that it has become diverted by success, a success whose technical virtuosity has cost dear. Some critics, perhaps unkindly, even argue that the new cognitive science, the child of the revolution, has gained its technical successes at the price of dehumanizing the very concept of mind it has sought to reestablish in psychology, and that it has thereby estranged much of psychology from the other human sciences and the humanities.
>
> 1990: p. 1

A major cause of this growing disenchantment is the dominance of computer models in conceptualizing the mind. Bruner refers to 'an interesting turning point' in his life in the mid-1980s, when he 'got to thinking about agency more and more,' while, he thought, psychologists talked about mechanisms a lot without talking about human agency (Olson, 2007: p. 149).

Bruner started to focus on the study of cognitive development in the late 1960s; and when he moved to Oxford in 1972 he moved away from laboratories' controlled environments to more natural settings where real people interact. He launched a project in which he observed mother–infant interactions in the process of language acquisition (e.g., Scaife and Bruner, 1975; Bruner, 1983a).

Through his research in cognitive and linguistic development, he increasingly came to appreciate the role of culture. The significance of culture in equipping the human mind, especially the role of the narrative mode of language use, turned him to 'cultural psychology,' and some regards his cultural turn a second revolution in psychology (Bakhurst and Shanker, 2001: pp. 1–2). He now looks to cultural practice in understanding the essence of our humanness. Against the mechanical or computational conceptions of mind, he highlights agency and intentionality in our mental operations. But he also thinks that these traits are mere potentials in us that need to be enhanced by cultural tools and realized in cultural contexts. He says, "to understand man you must understand how his experiences and his acts are shaped by his intentional states, and … the form of these intentional states is realized only through participation in the symbolic systems of the culture" (Bruner, 1990: p. 33). Thus he has been inquiring into the way people understand themselves and the world, how they weave meanings through narratives, and the processes of their situated actions in cultural settings.

One may well recognize a thread in his seemingly divergent range of research from psychological experiments in laboratory to the observation of linguistic development in natural settings to the nature of narrative processes employed in legal procedures. It is, in short, his interest in what makes us human.

One may also notice that his style of work is very dialectic. As he himself admits, he likes starting up new programs without bothering to work out every detail to the end, and he leaves them to others. Barbara Rogoff, David Olson, and Patricia Greenfield are the examples of researchers who are working on such programs (Shore, 1997: pp. 17–20, 24; also, Bruner, 1980: p. 111). Just as he had earlier rejected the behavioral and experimental approaches to psychology and launched the Cognitive Revolution, a few decades later he attempted another new approach in cultural psychology. He keeps on finding new problems, new ways of looking at things, and keeps conversation going.

Theoretical Sources and Inspirations

In his autobiography, Bruner names John von Neumann (computer science), Herbert Simon (computer science), Noam Chomsky (linguistics), Jean Piaget (psychology), and Lev S. Vygotsky (psychology), among others as his intellectual heroes, because they prepared foundational ideas that recovered the study of mind from the dominance of the study of stimulus and response, conditioning, decontextualized behavior, and of environmental determinism (1983b: p. 60).

Besides these heroes, a special mention is due to his long-time colleague and friend George Miller and his idea of

cognitive constraints. In 1956, George Miller published an ingenious account of the constraints on our cognitive capacities. Miller's argument, along with others, such as Sir Frederick Bartlett's 'scheme theory' and Edward Tolman's idea of 'cognitive map,' gave Bruner the idea of the importance of strategy for humans, who had a very limited range of attention, perception, and memory, to process the overwhelming amount of information. Bruner discarded the traditional approach to the study of human cognition, whose typical example may be Hermann Ebbinghaus' study of memory that used the memorization of nonsense syllables. Bruner thinks that people like Ebbinghaus overlooked, first, the significance of the context in which such human cognitive functions as memory works, and second, the idea of agency seen in such aspects of human cognition as selection, organization, and strategy in memory and thought (1983b: pp. 97–98).

Bruner regards Jean Piaget as a great pioneer, even though he disagrees in details of Piaget's theory. He acknowledges Piaget's contribution in advancing our understanding of the developmental processes, because he replaced "[t]he old view that pictured the infant as 'random' in his actions and saw growth as constituting of becoming 'coordinated'" (1983a: p. 28).

One of the major ideas Bruner took from Piaget (and his collaborator Bärbel Inhelder) is that knowledge takes different forms at each developmental stage, and the acquisition of knowledge is not a process of incremental accumulation as behaviorism and associationism hold (Olson, 2007: p. 70). Unlike the Genevan psychologists, however, he does not think that the process of development occurs spontaneously. Here, Bruner sides with Vygotsky and Alexander Luria and thinks that the development is a result of enculturation; development happens outside-in rather than inside-out. And this view has important implications for Bruner's educational theory, as we will see later.

Somewhat similar to his attitude toward the Piagetian theory of development, Bruner develops his own theory of language acquisition by critically reviewing Noam Chomsky's nativist theory of linguistic development. Bruner believes that human competence in general is "both biological in origin and cultural in the means by which it finds expression" (1983a: p. 23). While he acknowledges, along with Chomsky, that there are some 'endowments' that provide "foundation processes that aid the child's language acquisition," he also thinks, unlike Chomsky, that none of these endowments generates language on its own. Thus Bruner advances the notion of the Language Acquisition Support System (LASS) to supplement Chomsky's Language Acquisition Device (LAD). Assuming that human beings are born with some propensity for linguistic communication, and that such a propensity may be efficient enough to be regarded as a LAD, Bruner says that it will not turn into a full-fledged language without a LASS, which is provided by the social world. "It is LASS that helps the child navigate across the Zone of Proximal Development to full and conscious control of language use" (Bruner, 1986: p. 77).

Bruner and Education

Outside the specialized field of psychology or cognitive science, people got to know Jerome Bruner through his educational theory and his involvement in the curriculum reform movement in the 1960s. His influence on education was most strongly felt in the 1960s and the early 1970s, and a good example is the fact that Project Head Start, which is now part of the American educational lexicon, is Bruner's brainchild, though he was not directly involved in the implementation of the program.

In the 1950s, a sense of educational crisis was already brewing in America. The center of the concern was declining academic standards in public schools. In the atmosphere of the Cold War and the scientific and technological rivalry between the United States and the Soviet Union, the American public felt that their public schools were not effective, or even failing, in educating citizens who were intelligent and knowledgeable enough to carry on the competition.

Among various factors that brought about the educational crisis, two should be mentioned. One was the dominance of progressivism, or a vulgarized form of progressivism that 'had degenerated into permissivism,' which allegedly caused the decline of academic content and standards (Olson, 2007: p. 65). The other had to do with the American tradition of local control of educational matters. That is, education professionals (teachers and local administrators), who were not particularly well informed in academic content areas or in learning theory, controlled the daily grind of schooling.

The so-called Sputnik Shock in 1957 added to their sense of crisis and led to the involvement of the federal government, researchers, and scientists in educational matters, and Bruner played a major role in this process. Bruner wrote *The Process of Education* as a chairman's report of the Woods Hole Conference (held in September 1959), which was organized by the National Academy of Science, and attended by a number of leading scientists and psychologists, to have a closer look at the new science curricula that had already been revised and implemented. The book was an instant success. While retaining the progressivist theme of students' involvement in their own learning, Bruner provided a theoretical framework to ensure also focused attention on academic content.

Bruner in *The Process of Education* presented a few innovative ideas, and they were (1) the importance of the structure of the discipline, (2) the idea of spiral curriculum, (3) the use of intuitive thinking along with analytic thinking, and (4) how students' desire to learn can be stimulated (the problem of motivation). In sum, the central idea that connects all these concrete proposals is seen in his remark "intellectual activity anywhere is the same, whether at the frontier of knowledge or in the third-grade classroom" (1977: p. 14).

Given the information explosion in the modern world, Bruner took it for granted that one had to acquire powerful learning and thinking skills and to acquire a taste for further, self-motivated, learning. The problem then is to figure out, first, how to motivate children for learning, and second, how effectively schools may equip students with powerful tools of knowing and thinking.

On the first task, Bruner thought that the traditional method of coverage was hopeless, and also thought that the Deweyan view of arousing children's motivation by connecting learning in the classroom with their daily experience outside school was not enough ("After John Dewey, what?" in Bruner, 1962). He

was also critical of the Piagetian view of readiness: waiting for children's motivation and capacity for learning to spontaneously emerge. He believed that the motivation can and should be stimulated and created, and that the best way to arouse students' desire to learn is to expose them to the world of real scientific or academic inquiry.

He thought that intellectual activity in young students was essentially the same as in first-rate scientists, and that the essential part of making study or inquiry self-rewarding was 'discovery.' Thus, the process of learning ought to be the process of discovery, and discovery of what he called the 'structure' of knowledge. In his view, mere accumulation of pieces of information will not give students either effective tools of thinking or motivation for learning. On the students' part, instead of being given disconnected, decontextualized pieces of information to memorize, students should better be encouraged to discover, as much as possible on their own, meaningful connections (structures) of knowledge. Each school subject or academic discipline has its own structure of knowledge, and structured knowledge has 'generativity' that would make the acquisition of further knowledge easier. Students were also encouraged to utilize different modes of thinking – 'intuitive' as well as 'analytic' – just like scientists, to first grasp a hypothesis by drawing on their hunches (albeit well-informed hunches; cf Bruner, 1977: pp. 56–57), and later confirm, revise, or reject the tentative conclusion by drawing on analytic thinking. These are essential features of real inquiry, which Bruner thought had unfortunately been neglected in school, and had better become the model for learning in school.

Young students, however, do not possess either the amount of knowledge or the skills of inquiry that research scientists do, and a sort of translation is necessary. Here, Bruner borrows from the Piagetian insight that the way children understand things is qualitatively different according to their age. So, the same topic can and needs to be presented to the child in different forms depending on what 'mode of representation' is dominant in the child, and the same topic will be covered at different timings (grade levels, etc.), using different 'modes of representation.' This is his famous idea of spiral curriculum; the same topic is learned by using different modes of representation and with increasing complexity as students' cognitive capacities grow.

In combining his beliefs that interest can be created and that there are ways to teach things to students effectively, Bruner makes a bold assertion in *The Process of Education*, "any subject can be taught to anybody at any age in some form that is honest." This is probably the most quoted and most sensational claim of his. I think that Bruner's point in this proposition is in the word 'honest.' It is true that progressive education in some cases did very well to engage children in school tasks, but the question still remained: are they really learning what's worth learning or what will enable them to understand the world and themselves better? Many answered this question in the negative and Bruner's proposals, encapsulated in this quote, seemed to offer the means to ensure the honesty part; that is, children not only have fun or excitement but also learn academically respectable content – in a word, academic 'excellence' (1960: pp. 9, 70; 1962: p. 119).

Bruner published a series of books on education in the 1960s and the early 1970s, starting with *The Process of Education*, which caused quite a sensation not only in the United States, but also around the world. His educational publications in those decades, in fact, inspired the curriculum reform movement. One of the projects in the movement was his famous *Man: A Course of Study* (MACOS), an innovative elementary social studies program. It was initially received favorably, but its anthropological approach stirred up some controversy, and MACOS was eventually removed from the public school curriculum (see Dow, 1991; for detailed accounts).

After a few decades, Bruner published in 1996 *The Culture of Education*. In this book, Bruner critically reviews some of his earlier positions by incorporating his later perspectives on cultural or folk psychology. For example, Bruner now rejects the idea of deprivation that underlined Head Start (the view that impoverished children lacked something that needed to be filled) though he still endorses the overall program (Bruner, 1996: p. 80; cf also, Geertz, 2001: p. 22).

Another change might be found in his reference to Dewey. Bruner's comments on Dewey were very critical in the 1960s and, many people regarded him as someone to replace Dewey. Now, however, he speaks more appreciatively of Dewey, and many, including Bruner himself, regard – I think rightly – him as an heir to the great American tradition of pragmatism (Olson, 2007: pp. 64, 161).

Today, Bruner's influence on educational discourse and practice does not seem as direct as it used to be in the 1960s. While in his earlier career, he was much more concerned with implementing his educational ideas (as in MACOS), his educational work in more recent years is rather descriptive and his influence indirect. Many educators continue to get inspirations and borrow insights from Bruner, but very few try to actually implement his ideas as he did in the 1960s and the 1970s (Takaya, 2013).

Conclusion

Today, Bruner's presence is not felt as strongly as it used to be. Nevertheless, in the hands of his former students and colleagues, the theoretical seeds he planted continue to grow in various ways. A few examples may be cultural psychology, the notion of school as a community of learners, and the significance of narrative in understanding the world and ourselves. Also his former students and colleagues have been making significant impacts on education and psychology (e.g., Howard Gardner, David Olson). And most amazingly, as Gardner, one of his former students, comments, Bruner, at well past his 90s mark, still is the "youngest and most eager child in his class" (Gardner, n.d.).

Abstract

Jerome Bruner is one of the founding fathers of cognitive science, an interdisciplinary approach to the study of the human mind. Cognitive science originally grew out of researchers' discontent with the behavioral and experimental approaches in the early twentieth century. By integrating findings in various fields such as psychology, philosophy, anthropology, neuroscience, information theory, and linguistics, they now understand how the human mind develops and works from diverse and richer perspectives. This article examines Bruner's contribution to the development of cognitive science and major features of his theory of cognitive development.

The Birth of Cognitive Science

Cognitive science grew out of psychology in the mid-twentieth century, and its founders, including Jerome Bruner, generated it out of their discontent about the way psychology was conceived and practiced – what the central concerns of psychology ought to be and how psychological problems were conceptualized and examined. In criticizing existing forms of psychology, cognitive science developed as an interdisciplinary approach to 'long-standing epistemological questions' (Gardner, 1987: p. 6) in such diverse disciplines as psychology, philosophy, anthropology, computer science, information theory, linguistics, and neuroscience. Researchers interested in the study of the human mind today tend to use the designation *cognitive science* or *cognitive sciences*, instead of psychology, to imply that psychology alone, let alone the narrow approach of behaviorism, can enable us to understand the nature and development of the mind adequately.

When cognitive scientists discuss cognition, they usually focus on *human* cognition. When discussing cognition, Bruner, for example, means distinctively human forms and processes of perceiving, thinking, and learning (1983b: p. 122). Howard Gardner (1987), who was one of Bruner's assistants, adopts the same criteria in writing arguably the most comprehensive study available on the history of cognitive sciences; he writes, "Though the term cognitive science is sometimes extended to include all forms of knowledge – animate as well as inanimate, human as well as nonhuman – I apply the term chiefly to efforts to explain human knowledge" (p. 6). Michael Cole and Sylvia Scribner (1974) in their introductory textbook to cognitive science also write that their focus in researching and writing about cognition is the acquisition, transformation, and use of information by humans (Chapter 1). Cognitive scientists today go beyond the traditional scope of psychology to examine various elements that constitute our cognition, such as language acquisition, concept formation, metaphor, social and cultural foundations of our mental operations, etc.

The sources of cognitive scientists' discontent about the then-dominant type of psychological research – behaviorism and experimental psychology – were two; first their units of analysis were too small, and second, they were too close to environmental determinism. In short, they felt the absence of the mind, the very essence of humanness, left much of this work impoverished.

On the first point, behavioral and experimental approaches avoided questions of mind because it is not observable (a bit like a drunkard who is looking for his lost car key under the streetlamp precisely because he can see things there). Accordingly, those approaches missed essential features of human perception and thinking; an example of this was the idea of selectivity in perception or of strategy of thought (cf Bruner and Postman, 1949: p. 206; Bruner, 1983b: p. 276).

For Bruner, and his like-minded colleagues, a stimulus is not equivalent to perception, and human cognition is not reducible to the largely predetermined patterns of stimuli and responses observable in animal studies. Human beings have what may be appropriately called minds, and they can act on their environments to open up new possibilities.

Bruner began to use at least hints of such ideas as agency and purposiveness as early at his undergraduate years at Duke University. There he took courses (besides those taught by his mentor, William McDougall) from Donald Keith Adams and Karl Zener who had learned Gestalt psychology from Wolfgang Köhler, Max Wertheimer, and Kurt Lewin. Two books that influenced him at that time in this same direction were Frederic Bartlett's *Remembering* (1932) and Edward Tolman's *Purposive Behavior in Animals and Men* (1932).

Another inspiration came from Robert Oppenheimer in 1951, when Bruner was at the Institute for Advanced Study on sabbatical. Oppenheimer remarked, that "units of analysis in science usually turn out to be much larger and more inclusive than one at first expects." Bruner and his coauthors came to appreciate 'the appropriateness of his remark' as they worked on *A Study of Thinking* (Bruner et al., 1956: Preface, p. xix). The appropriate units of analysis they found were not stimulus and response in individual instances, but the 'overall patterns of responding' (see the quote from Gardner below) that is, the process of perception or thought infused with selectivity and strategy. In coming to this view, they

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23095-X

borrowed from such neurophysiological concepts like 'gating,' 'tuning,' 'models,' and 'intentions' (Bruner, 1983b: p. 99). Howard Gardner writes on the innovation that Bruner and his coauthors brought about in the book:

> [Bruner, Goodnow, and Austin] ended up analyzing the informational properties of long sequences of acts called "strategies." It had turned out that the best way to account for individual performances was in terms of these overall patterns of responding over many trials rather than of particular responses to a particular stimulus configuration. This was the most iconoclastic – and the most influential – aspect of the work. (1987: p. 94)

In a famous study on the perceived sizes of coins, Bruner and Goodman (1947) showed that the felt value of the coin affected the perception of the size of the coin; children from poor families tended to overestimate the sizes of coins, compared to children from affluent families. Perception, therefore, is not raw data. It is infused with selective mechanisms, intentions, and expectancies; in short, what we call the 'mental.' Bruner elsewhere remarks, "Stimuli … do not act upon an indifferent organism… The organism in perception is in one way or another in a state of expectancy about the environment" (Bruner and Postman, 1949). We may notice that positing things mental, subjective, or intentional is a critique of environmental determinism that behaviorism inherited from the classical empiricism or sensationism of such philosophers like John Locke and Claude Adrien Helvetius, distant predecessors of 'scientific' psychology against which Bruner and his colleagues were revolting.

For Bruner, it is obvious that '(m)ind in some operative form is there from the start,' and the more important task for psychology is to analyze 'the conditions that produce human minds that are richer, stronger, and more confident' (1983b: p. 152). As he went on with his research into the 1980s and the 1990s, he increasingly shifted his focus from the processes working inside the individual mind toward more cultural, dialectical types of mental formation and operation. The central thread of his research is, however, clear; he finds excessive objectivism, reductionism, straightforward causations, and determinism in contemporary psychological research, and tries to restore a richer conception of what it means to be human.

Bruner, looking back on the mid-century when he and George Miller started the Center for Cognitive Study, says:

> I suppose everyone has a somewhat different notion of what the "center" of psychology is. We had our idea. We thought it was concern for the distinctively human forms of gaining, storing, transforming and using knowledge of all sorts – what makes humans human. Call them the cognitive process. (1983b: p. 122)

Miller (2003) also remarks, by quoting Noam Chomsky, that they thought, "defining psychology as the science of behavior was like defining physics as the science of meter reading." People like Bruner, Miller, and Chomsky used 'cognitive' in their center's name "defiantly, when most respectable psychologists at the time still thought cognition was too mentalistic for objective scientists" (Bruner, 1983b: p. 124).

In searching for the essence of our humanness (i.e., in searching for mind as the title of his autobiography suggests), he has consistently highlighted such 'mentalistic' concepts as intentionality and strategy, but his focus in his early career seems to have been largely on the *intra*psychic functions, so to speak. In his later career, he shifts his focus toward more *inter*psychic aspects of the mind such as culture and intersubjectivity. Bruner's cognitive theory, particularly since the 1980s, is marked by its cultural approach, because he thinks that we become human by and through culture. He emphasizes that the human mind becomes what it is by internalizing cultural tools – among which language is prominent – available in the society where one is born and to live. He says, "To treat the world as an indifferent flow of information to be processed by individuals each on his or her own terms is to lose sight of how individuals are formed and how they function" (1990: p. 12). Influences of Vygotskyan psychology are evident here, but he also integrates views from anthropology, philosophy, linguistics, etc.

By emphasizing the importance of 'outside-in,' however, he does not go to the extreme of environmental determinism of Locke and Helvetius, or of James Watson and B.F. Skinner. Bruner also emphasizes, again without going to the other extreme of nativism which Jean Piaget's or Noam Chomsky's theories may do, that there are some predispositions that lead human infants naturally toward interaction and communication with people around them and learning from cultural resources. In Bruner's view, human nature and culture are seamlessly connected, and this is a view which David Bakhurst develops in recent years, albeit critically, by drawing on the philosophy of John McDowell as well as on Bruner, as an idea of culture as 'second nature' (Bakhurst, 2001; particularly, pp. 188–190; cf also, Bakhurst, 2011).

Major Topics in Bruner's Developmental Theory

In order to understand distinctive marks of Bruner's theory of cognitive development, it helps to have a look at his concrete ideas. In the following, I will review some of his major concepts and topics: (1) the idea of three modes of representation, (2) language acquisition, (3) the concepts he favors after his 'cultural turn,' and (4) constructivism.

Modes of Representation

Somewhat similar to Jean Piaget's idea of developmental stages, Bruner says that there are three distinctive modes of representation, enactive, iconic, and symbolic, and individuals acquire these modes one by one, in the order of enactive to iconic to symbolic, until in the end they become capable of all the three modes of understanding. Very young children who have not mastered their native language understand and communicate through behavior; then, they start using concrete

images; and finally they begin using symbols and can now engage in abstract thinking without necessarily relying on concrete objects or images. Bruner says:

> Human beings represent their knowledge of the world in three ways. One is through habit and action: knowing what to do. A second is through imagery: depiction of events and relations. Finally, we "know" things by representing them in a symbolic system like language or mathematics. Making progress in the mastery of any domain most often involved using all three modes of representation – typically progressing from enactive, through iconic, to symbolic. Indeed, understanding could be deepened by using all three modes, even (and sometimes especially) when they were in conflict with each other. If some modes were easier for the child than others, then the way of helping him across the "zone of proximal development" was to start with it and then move on to others. (1983b: p. 142)

The modes of representation have educational implications just like Piaget's stage development theory does. In teaching young children, teachers have to carefully observe which mode is dominant in the child they are teaching. Knowing the nature of these modes of representation and individual children's dominant modes would allow teachers to effectively convey what they have to teach.

Bruner's modes of representation, however, are not the same as Piaget's developmental stages, because while Piaget saw cognitive development as spontaneous, that is, as a result of internal or physiological maturation, Bruner sees it "as the consequence of learning to deal with the world in terms of progressively more advanced cultural forms and cultural modes of representation" (Olson, 2007: p. 69).

As to the causes of development, Bruner is unmistakably Vygotskyan, as clearly seen in his reference to the Vygotskyan concept of the zone of proximal development in the quote above, for he does not think that human cognitive development is 'spontaneous'; for him, psychological/cognitive development is not simply a function of physiological maturation. It is true that human beings are uniquely predisposed to picking up 'tools' from their surrounding culture to make them their own psychological tools, but, nonetheless, internalization of cultural tools must take place for psychological development to take place.

Having said that, however, it should be noted that Bruner shares an idea of cognitive development with Piaget and Bärbel Inhelder in that they consider development as a process of transformation rather than a mere accumulation of information. Bruner is in agreement with Piaget on the importance of this transformation, but unlike Piaget, he thinks that the moving force of the development is culture, in which language is prominent. Bruner wrote, "learning to encode the world linguistically and then to operate on language rather than on the world – that was the ultimate stage of cognitive development" (1983b: p. 161; cf also, Olson, 2007: p. 21). Bruner's theory of cognitive development is developmental in a Piagetian sense to the extent that it has a sense of direction in which development ought to go and involves a notion of qualitative changes, but it is also Vygotskyan in that the development is brought about by the acquisition of cultural tools.

Language Acquisition

While acknowledging that human beings have innate endowments for language acquisition, Bruner does not go so far as Noam Chomsky's nativism. Tomasello writes:

> In opposition [to Chomsky's Language Acquisition Device, LAD], Bruner posited that human beings come into a world that is already structured culturally and linguistically, and their long period of immaturity is designed precisely for them to acquire the particular cultural and linguistic conventions into which they are born. (2001: p. 36)

One of the endowments that human beings are born with is their propensity for shared attention. Scaife and Bruner (1975; also, Bruner, 1983b: p. 170) showed that infants, even in their first year of their lives, could direct their attention to common objects with their caretakers. They also found that in engaging in such a play like peekaboo, infants can quickly learn to reverse hider and seeker roles with their mothers. Clearly, human infants are predisposed to treating others as minded creatures, interacting with others, and communicating. Their findings are also quite inconsistent with Piaget's picture of very young children as very 'egocentric' and of 'egocentricity' being overcome by language acquisition (Tomasello, 2001: p. 36). Bruner says:

> In the end, I came to the conclusion that the need to use language fully as an instrument for participating in a complex culture (just as the infant uses it to enter the simple culture of his surround) is what provides the engine for language acquisition. The genetic "program" is only half the story. The support system is the other half. (1983b: p. 173; cf also, Geertz, 2001: p. 21)

Besides the traditional focus on syntax ('well-formedness') and semantics ('(language's) capacity to refer and to mean'), Bruner highlights the importance of pragmatics in studying language acquisition, that is, "how to get things done with words" (1983a: pp. 17–18). While he thinks that the three facets are interdependent and inseparable, he, by emphasizing the significance of pragmatics, highlights the point that "language acquisition 'begins' before the child utters his first lexico-grammatical speech" (ibid., p. 18). Language is one of the means of 'getting things done,' though it is a very powerful one.

Roughly speaking, in the 1970s (when he was at Oxford University), Bruner studied the process of linguistic development in infants. In the 1980s, he broadened his research from linguistic development in the individual to linguistic practices in wider culture (Tomasello, 2001: pp. 33–34). Since his youth, Bruner has consistently refused the classical view on the nature of human cognition that regards perception or sensory input as raw data and thought as an addition; for Bruner, psychology is not a mere addition to physiology. Human mind becomes what it is by participating in culture and developing its potential through culture. Thus, for Bruner, and as is acknowledged widely by cognitive scientists and philosophers today, psychology cannot be constructed on the basis of the individual alone (Bruner,

1990: p. 12). It then makes sense that, in the 1980s, after he had studied human cognition as a property solely of individuals, he shifted his attention increasingly toward culture's role in the formation of our cognition; how language functions in cultural practices. Thus, he now explores the uses and significance of narratives in meaning making (and his most recent research interest is in how narratives work in the context of legal procedures).

Another important turn his research brought about was a perspective on intersubjectivity, that is, how people understand what others are perceiving and thinking ('Did you see what I saw?'; cf Olson, 2007: p. 25). Thanks to the research on shared attention, we now know that human beings at a very young age already 'know' others are minded beings. This is again a refutation of the Piagetian belief on children's egocentricity and the notion of decentering as development, and shows how humans are predisposed to communication and participation in culture.

This perspective on intersubjectivity has important implications for education. Piagetian theory of children's egocentricity suggests that children must acquire knowledge of the world directly, unmediated by language, and on their own, unassisted by more experienced members of society. According to Bruner, this position underestimates the resources available for even very young children and makes the task of education unnecessarily difficult. Children are naturally prepared to enter the world of shared meanings, and they will later be assisted by language. Bruner says, "Most of our approaches to the world are mediated through negotiation with others" (1986: p. 68), and intersubjectivity is the key to entering the 'negotiation with others.'

Culture and Narrative

Even though Bruner has consistently appreciated how culture shapes the mind, he was more cautious about the constraints culture might impose on our thoughts, values, and perspectives in the 1960s and the 1970s. That's why he thought it best to incorporate the most sophisticated form of cultural activities – first-rate research in natural and social sciences – into school curricula when he led the curriculum reform movement in the United States in the 1960s (cf his famous ideas of 'discovery learning' and 'the structure of disciplines'; see my article 'Jerome Bruner' for more). In recent years, however, he is more trusting in the resources available in our familiar, everyday culture ('folk culture') for the development of our cognitive capacities. He writes in 1986:

> It would not be an exaggeration to say that in the last decade there has been a revolution in the definition of human culture. It takes the form of a move away from the strict structuralism that held that culture was a set of interconnected rules from which people derive particular behaviors to fit particular situations, to the idea of culture as implicit and only semiconnected knowledge of the world from which, through negotiation, people arrive at satisfactory ways of acting in given contexts. The anthropologist Clifford Geertz likens the process of acting in a culture to that of interpreting an ambiguous text. (p. 65)

While he used to appreciate the power of scientific and academic aspects of cultural activities for the purpose of cultural transcendence, he is now more trusting of more mundane aspects of culture as well.

The end of cognitive development, in his more recent formulations, is the acquisition of capacities with which people not only function well in the social and natural environment but also are able to, if necessary, transcend the limit that their culture or society imposes. He used to think that this kind of capacity was attained best through acquiring the knowledge and skills embodied in academic disciplines (what he calls the 'paradigmatic' mode of thought), but he now thinks that resources available in our folk culture (the 'narrative' mode) are no less potent.

Culture embodies 'a set of values, skills, and ways of life' and it is the 'toolkit' for sense making and communicating (Bruner, 1996: p. 3). Cultural tools enhance our presumably natural endowment in action, perception, sense making, and thought (Bruner, 1966: p. 126; cf also Bruner, 1971: p. 53). Culture provides tools and contexts with which individual members make sense of and appraise incidents and phenomena. As such, on the one hand, it imposes a constraint on endeavors of the individual mind; just like our native language imposes a certain limit on the way we think and communicate. On the other hand, culture does not lack resources for the individual to transcend to some extent the limits imposed either by the putative human native endowment or by culture itself. Bruner points out, for example, that all known languages have ways to indicate 'the might-or-might-not-be, the *possible*' (in Olson, 2007: p. 5. emphasis in original). He also says that people who are adept at various modes of language, such as metaphor and irony, seem to be much less constrained by the syntactical structure of the language (Bruner, 1996: p. 18).

It seems, then, very natural that he is now more interested in exploring the possibilities of the latter, particularly the uses of narrative in legal procedure.

Constructivism

The epistemological position of constructivism is not Bruner's invention. Bruner's name, however, is often associated with it. Constructivism, in a nutshell, holds that what we may call reality, truth, or knowledge is not something fixed, eternal, or objective in a strictest sense, but it is in fact what we construct according to our particular perspective or purpose. Bruner writes:

> The constructivist view, that what exists is a product of what is thought, can be traced to Kant, who first fully developed it. Kant, in turn, attributed his insight to Hume's discovery that certain relations among things in the real world could not be attributed to events but rather were mental constructions projected onto an "objective world." (1986: p. 96)

Unlike such predecessors' assumptions, however, constructivists today argue that our cognition cannot be neatly divided into raw sensory data and thought, and our knowledge of the world cannot be founded on incorrigible foundations – there is no such thing as raw data. Accordingly, knowledge is not a mere mirroring of things 'out there' (Bruner, 1971: p. xi). Rather, Bruner believes that knowledge

is 'justified belief' and a model we construct for specific purposes (1996: p. 59). Although he does not take the position of free-for-all relativism or extreme subjectivism (ibid., p. 61), he firmly believes that knowledge is revisable and accommodates multiple interpretations. Knowledge of the world or what we know as the 'reality' of the world is a tentative result of negotiations between our individual perspectives and more-or-less stable, established systems of meanings that traditions and cultures have established. Knowledge, therefore, should rather be understood in terms of meaning making, which is inseparable from communicating (1996: p. 3). In refusing the assumption that knowledge has incorrigible foundations and in adopting the criteria of perspective and purpose in determining what is right or wrong, Bruner inherits the pragmatism of William James and John Dewey, and is in agreement with such contemporary philosophers as Nelson Goodman (one of Bruner's colleagues at Harvard's Center for Cognitive Study) and Richard Rorty.

Piaget and Vygotsky

Although Bruner's theory, particularly his theory of cognitive development in later years, is more akin to Vygotsky's than to Piaget's, he does not discard Piaget's perspectives completely; Piaget is still one of Bruner's intellectual heroes (1983b: p. 60). In an essay in *Actual Minds, Possible Worlds* (1986), he critically appraises the psychological theory that pictures very young children as 'egocentric' and the process of development as a process of decentralization in the light of his findings on the emergence of intersubjectivity in early childhood (Chapter 4).

Considering, for example, the ease with which very young children master 'deictic shifters,' which require the grasp of the viewpoints of the person with whom one is interacting (e.g., 'here' used by me is close to me, while 'here' used by you is closer to you), the Piagetian picture of children as 'self-centered' is inadequate. Bruner then describes the problems of the major premises of Piagetian view, for example, its view that the individual mind encounters the world unmediated. Nevertheless, Bruner does not forget to add that these premises are rather arbitrary and partial than completely wrong. He says, "they are true under certain conditions, false under others, and their 'universalization' reflects cultural bias" (ibid., p. 61).

Unlike Piaget, Vygotsky does not think that cognitive development is automatic or something that happens without regard to cultural and social contexts. Bruner appreciates Vygotsky for his recognition of the role of cultural context in human development (1983b: p. 139). From a Vygotskyan perspective, what brings about children's cognitive development is cultural input and social interaction as much as internal, physical maturation. As such, it is crucial that children are engaged with the people and the world around them. You just do not wait for their interest to show up; you can and should create and stimulate interest (Bruner, 1962: p. 117).

Though Bruner is not without some disagreements with Vygotskyan psychology (Olson, 2007: p. 152), his cognitive and developmental theories are, on the whole, closer to Vygotsky's than to Piaget's, particularly in more recent years.

Cultural Turn

As Bakhurst and Shanker (2001) point out, Bruner was involved in two revolutionary movements in the study of the human mind (Bruner et al., 1956: Preface, p. xix). In the 1950s, when the dominant psychological approaches disregarded the mind almost altogether and focused on the correlations of stimuli and behaviors, Bruner and others incorporated conceptual schemes and research findings from various fields to restore the concept of the mind and launched cognitive science.

A few decades later, however, Bruner came to notice that cognitive science was now so caught up with computational models – ironically, given that these had earlier been among the moving forces to restore the notion of mind – and instigated a cultural turn by once again examining the characteristics that make up our minds. Bakhurst and Shanker write:

> [The Cognitive Revolution] restored to psychology the inner life of the mind after decades of arid behaviorist objectivism … But cognitivism had become so enamoured of conceptual computational models of the mind that it had replaced behaviorism's impoverished view of the person with one no better; human beings as information processors. In response, Bruner argued forcefully that meaning is not a given, but something made by human beings as they negotiate the world. (2001: pp. 1–2)

While Bruner has always been attracted to the notion of culture since the earliest days of his psychological research, he highlighted what he calls the 'paradigmatic' part of culture such as sciences as practiced by first-rate researchers who were equipped with well-structured knowledge of their fields. In more recent years, however, he finds at least equally potent resources in more mundane aspects of culture. He says:

> Well, I think the two principals that have changed are, first, I became much more mindful in the 1970s about alternative modes of thought. These modes of thinking are all narrative and they are all narrative not only in thinking but in the way we justify and structure our culture. And second, I have become much more deeply concerned about the nature of human culture and the way in which culture shapes individuality and the way in which individuality works back into the culture.
>
> Those are the two big changes as I shift toward narrative. I think I would add a third change, an emphasis on agency. Narrative, culture, and agency. (Bruner in Olson, 2007: p. 175)

Bruner has consistently highlighted the importance of the way the human mind goes beyond the information given as well as the importance of recognizing how our minds are shaped by social interaction and culture. In this way, he tries to overcome the limitations of behaviorism and its logical implication, that is, environmental determinism, and retain the idea of human agency.

Conclusion

Bruner characterizes his own approach to the study of mind as follows:

> … I have always thought of myself as an 'intellectual' first, and then a psychologist. An intellectual is somebody who follows his ideas where they may lead without regard to disciplinary boundaries and who, having done so, accepts the consequences of his conclusions in how he thinks, feels and acts personally. (1983b: p. 230)

In my view, this is precisely what brought about the cognitive revolution in the mid-twentieth century and made him a central figure in that movement that revolutionized psychology or the study of mind. As he describes himself as having a strong 'left-hand' – that is, intuitive rather than analytic – tendency, he likes to open up new ways of thinking and start up new programs of research without bothering to pursue every single detail and implication to the end; he simply leaves that to others. These topics are now in the hands of his former students, younger colleagues, and new generations of researchers (such as Howard Gardner, David Olson, and David Bakhurst), and they in turn keep the Brunarian spirit alive and explore the topics in a new light.

Abstract

Buddhism began a humanistic and individualist set of practices for salvation, a missionary religion which, in the course of its 2500-year history, has encompassed meditation, philosophy, ritual, art, ethnonational identities, and politics. The interaction and changing relationship between Buddhism's monastic leaders (monks, nuns) and the laity, and in particular kings or other secular authorities, has been a leitmotif of Buddhist history.

Buddhism is one of the world's three great missionary religions (the others being Christianity and Islam). It has assumed a great variety of social and ritual forms as it has spread throughout Asia and (since the end of the nineteenth century) the world. It began as a humanist and individualistic soteriology (religious doctrine of salvation) that preached the abandonment of ordinary householder life and its associated rituals. Monks and nuns renounce work and worldly activity; lay people support them in return for spiritual and ritual services. Whether the forms of ritual and religious life that developed for lay people should be seen as fully Buddhist or as some kind of 'second best' is an important part of debate over the interpretation of Buddhism between textual and more fieldwork-oriented scholars, as well as among Buddhists themselves. In both the modern and premodern eras, Buddhism has played an important but changing role in defining national identity in Tibet, Sri Lanka, Thailand, Cambodia, Laos, and Burma. In Japan, after 1868, the state attacked Buddhism as foreign and antinational, without being able to destroy it entirely. Everywhere revitalization movements in the modern period have tended to stress the rationalist and egalitarian parts of the Buddhist message; meditation has, for the first time, become a mass phenomenon practiced as much by lay people as by monastics.

Of the world's three great missionary religions (Buddhism, Christianity, and Islam), Buddhism is the oldest. It was one of a number of universalist soteriologies that emerged in the Gangetic Plain of north India in the sixth and fifth centuries BCE along with cities and kingdoms. It spread throughout Asia between 250 BCE and CE 1200. Thereafter, it began to go into decline in some places, eventually dying out in India, the land of its birth (except in the Kathmandu Valley, Nepal); in other places it went through cycles of decline and revival, culminating in newly invigorated and often innovative revivals in the modern era. In the nineteenth century – partly because of perceived similarities to and contrasts with Christianity – it proved to be powerfully attractive to many Westerners, an attraction that continued and grew in the twentieth century. But there are also underlying differences between Christianity and Buddhism which, when overlooked, lead to serious misunderstandings.

From a sociological viewpoint, Buddhism can be seen as an individualist and humanist soteriology (salvation religion) that developed a variety of communal forms and worldly orientations in different settings. It has legitimated many elaborate hierarchies; in modern times, many Asian intellectuals interpret it as an early form of egalitarian socialism. For many, meditation is the heart of Buddhism (Carrithers, 1983); in other places and times, elaborate ritual has been, and remains, more important. Some see vegetarianism as central to Buddhism; yet many Buddhists eat meat. Everywhere Buddhism is centrally concerned with death and salvation; but in some places, notably (but by no means only) in East Asia, Buddhist temples have become deeply involved in providing rituals for worldly protection and winning personal advantages. Most Buddhists take very seriously the notion of rebirth in accordance with the morality of one's actions; but in East Asia, the influence of Confucianism means that moral notions are usually divorced from the idea of rebirth.

The Buddha, His Teaching (Dharma), and His Community (Sangha)

Buddhist tradition is unanimous that the Buddha was born in Lumbini in southern Nepal and died, at the age of 80 years, in Kushinagar, India. The Theravada tradition maintains that he died in 543 BCE, and this date has become widely accepted by Buddhists: in 1956 the 2500th anniversary of the Buddha's death was commemorated in Nepal with delegations from around the world. Western historians of Buddhism have long rejected this date as too early and thus many textbooks give dates between 486 and 460 BCE. Recently, it has been argued that the correct date is probably around 400 BCE.

'The Buddha' means 'the awakened one'; the historical Buddha's family name was Gautama and according to later sources his personal name was Siddhartha ('he who has achieved his aim'). Buddhists believe that in principle anyone can become enlightened and teach others, and that there have been and will be many other Buddhas in different world ages and in different worlds. According to the tradition, the Buddha's father knew from a prophecy that his son might abandon his kingdom to become a great spiritual teacher and therefore isolated him within the palace, attempting to surround him with nothing but pleasure and ease. One day, however, he managed to escape and saw an old man, a sick man, and

a corpse. These 'three signs' alerted him to the existence of suffering and death, and he resolved to seek a way beyond them. He left the palace at night, cut off his own hair, abandoned his clothes, sent away his servant and horse, and set out to seek enlightenment. He spent 6 years experimenting with different teachers, before coming to see that mortification of the body was as bad as self-indulgence. He realized that a Middle Way was necessary – eating once a day, enough to maintain the body without overindulgence – and this led him to attain Enlightenment in Bodh Gaya, India, at the age of 35 years. Being enlightened – an aim that he shared with other renouncers of the time – means escape from the otherwise endless cycle of rebirths.

He gave his first sermon, to his first five disciples, in Sarnath, near Banaras in India, on the Four Noble Truths: the existence of suffering, the arising (cause) of suffering, the end of suffering (nirvana), and the path to achieve it. Nirvana is the 'blowing out' of the passion, hatred, and delusion with which we are on fire (and from which we suffer). The metaphor of fire refers to Brahmanical thinking: the Buddha took over much of the Brahmans' vocabulary while radically changing its meaning by ethicizing and universalizing it (Gombrich, 1988). The path to nirvana consisted of three stages: morality, meditation, and wisdom. In order to practice the latter two stages, and to attempt to attain enlightenment in this life, it was (until modern times) usually thought necessary to renounce the world, that is, to abandon, like the Buddha himself, the life of a householder, and live with other celibates: monks or nuns. The role of lay people was to practice morality and to support monks and nuns; by doing so they could improve their karmic state and attain better rebirths in future, eventually going on to attain enlightenment themselves. Later, many Buddhists came to believe that the world had declined to such an extent that even monks and nuns could not attain enlightenment, and they too should seek better rebirths.

At his death, the Buddha entered full nirvana and was not reborn. His remains were cremated and the ashes were divided between eight different lay groups and enshrined in *stupas*. Later, the remains of other prominent Buddhist clerics were similarly enshrined and these places, or smaller *caityas* modeled on them, became the characteristic places of Buddhist worship.

To facilitate a life of self-control and meditation, the Buddha founded his Sangha or Monastic Community. All Buddhists 'take refuge in' the Three Jewels, which are the Buddha, the Dharma (his Teaching), and the Sangha. Members of the Sangha are governed by 227 Vinaya rules (in the Theravada tradition; other traditions have 250 or more). These rules cover the correct behavior of monks; the nuns have their own Vinaya, with even more rules. This way of life appealed mainly to those of high status: although there were low-caste converts within the Sangha, high castes predominated. It was, as Max Weber (1958[1916–17]: p. 371) remarked, a 'genteel' (*vornehm*) soteriology.

Every fortnight monks are supposed to come together to confess any infractions of the rules and then to recite the rules together. However, in Theravada Buddhism there was originally little enforceable hierarchy. Monks do not promise to obey anyone. Deference is owed on the basis of seniority to monks who have been ordained for longer, and to one's teachers, but that is all. Ecclesiastical hierarchies have emerged in many Buddhist countries, but they are not prescribed in the Vinaya.

Despite the fact that, in practice, monks frequently maintain close ties with their kin and often carry on secular occupations, the institution of celibacy was to have weighty consequences for societies that adopted the Buddha's teaching. In Tibet it is estimated that before the 1950s 10–12% of the male population were monks, and a further 10–15% were noncelibate Buddhist practitioners. In Tibet and the Theravada countries, the history, as written in the premodern period, was the history of the Sangha. The issue of monastic property, and its transmission, is important in all Buddhist countries, with a variety of solutions being adopted.

By the standards of his day, the Buddha's teaching was individualistic, humanist, egalitarian, and rationalist. It was individualistic in that individual persons had their own karmic trajectory, which they could work to better by good actions or to harm by bad. There was no question of any higher power or other person granting salvation. It was humanist in that it debunked the Brahmans' claims to higher purity and spiritual status on the basis of their birth; it denied the efficacy of ritual (especially animal sacrifice), ecstatic trance, or worshipping gods in order to obtain salvation. Only one's own efforts will do. It was egalitarian in that all human beings have an equal chance to start out on this path (and humans are superior to gods in this respect: gods, though powerful, have to be reborn as humans to have a chance of achieving nirvana). It was rationalist in that the Buddha favored openness (in contrast to the secretiveness of the Brahmans, whose learning was available only to other Brahmans); and he stressed the need to try out doctrines for oneself and a rational ethic of helpfulness to others.

Thus, modernist reformers in the nineteenth and early twentieth centuries could relatively easily represent Buddhism as a rational and scientific belief system, as a philosophy and not a religion, as unconcerned with the existence of God or gods, and as implying social reform and development. However, most Buddhists have believed in gods, have practiced ritual in order to overcome misfortune and in order to benefit the dead, have regarded their faith as a religion, and have accepted socioreligious hierarchies. All the evidence shows that these practices are as old as Buddhism itself, and the modernist interpretation of Buddhism should be viewed as just that: as modernist and as an interpretation.

The Spread of Buddhism

At the beginning, Buddhism was just one of many different schools of renunciatory (i.e., renouncing earthly pleasures) philosophy. With its universalism and its teaching of careful attention, it seems to have appealed to townspeople and merchants, and to have spread with them throughout the Indian subcontinent. It emerged to prominence through the actions of the Emperor Ashoka (reigned c.268–239 BCE) who ruled most of present-day India. Though he protected all religions within his realm, his inscriptions advocate the Buddhist virtues of nonviolence, hard work, and consideration for others. He may well have seen Buddhism as a means of binding his enormous empire together and he sent out Buddhist

missionaries in all directions, including to West Asia (the Middle East). Buddhist tradition remembers Ashoka as the ideal Buddhist ruler and he became the model for many subsequent rulers attempting to reform the Sangha.

As Buddhism spread, different schools and ordination traditions emerged naturally, simply through geographical separation. The Buddha's teachings were preserved orally. This explains their repetitious character: they were only preserved because monks learned to recite them, and preservation of the canon quickly became a prime raison d'être ('reason for existence') of monastics. Writing probably did not yet exist in the Buddha's day. The earliest compilations of teachings were not systematically written down until the first century BCE, but long before that they had been organized into three 'baskets' (*pitaka*): the Sutta Pitaka, preserving the Buddha's teachings; the Vinaya Pitaka, preserving his rulings on the way of life of the Sangha; and the Abhidhamma Pitaka, which claims to present the teaching literally and systematically, and dates from after Buddhism was already established. (On internal evidence some of the Sutta Pitaka and much of the Vinaya Pitaka must also postdate the Buddha himself.) From time to time monks would come together to chant and check on each other's recitations. The early Buddhist councils were about fixing the Buddhist canon and debating minor differences that had arisen over monastic discipline. As far as the Buddhist laity was concerned, the central teachings were encapsulated in narratives about the Buddha's life, and particularly those concerning his 550 past lives contained in scriptures known as Jatakas and Avadanas; many of the latter were composed much later than the canon.

Among the many early Buddhist traditions, one was the Theravada, meaning 'doctrine of the elders,' so called because they considered themselves the most conservative. This is now found in Southeast Asia and Sri Lanka. Other schools had more adherents in India, especially in the northwest, from which China and Tibet received their missions, but Buddhism in what is now Pakistan, Kashmir, and Central Asia died out after the arrival of Islam. Consequently, Theravada Buddhism is the only form of pre-Mahayana Buddhism to survive into the modern world.

Although there are some small disagreements, the vast mass of Theravada scriptures, preserved in the Pali language, are shared and agreed upon in the Theravada countries. Pali was close to the local vernaculars of the Buddha's environment and the Buddha rejected use of the Brahmans' holy language, Sanskrit, both because of his policy of openness and because Sanskrit was held to be unchanging throughout time, which fundamentally contradicted the Buddha's teaching of impermanence. But as Buddhism spread, and as the spoken languages of north India evolved, Pali quickly became a purely scriptural and liturgical language, just like Sanskrit, and lay people became dependent on monks to expound the teaching to them.

Mahayana Buddhism

Around the turn of the Common Era an entirely new form of Buddhism arose in northwest India. It called itself the Mahayana. This is conventionally translated as 'The Great Vehicle' but equally means 'the great path or way.' It introduced a whole raft of new scriptures, now composed in a form of Sanskrit, which was supposed to date from the time of the Buddha himself; some claimed to have been hidden by him until people would be ready for them. The Mahayana reinterpreted the term *bodhisattva*, which for non-Mahayanists essentially means 'a future Buddha.' Mahayana Buddhism posited the existence of numerous powerful, celestial *bodhisattva*s. The most important of these was Avalokiteshvara, the embodiment of compassion, who would appear to people in their hour of need and save them from disaster. In China he came to be thought of as female and became the goddess Kwan Yin (Kannon in Japan). The Mahayana, unlike earlier forms of Buddhism, was most definitely based on a cult of the book: by this time scriptures were holy objects to be enshrined and worshipped as well as read.

The Mahayana introduced a revolution into the moral code of Buddhism, because it encouraged all Buddhists, whether monks or lay people, to aspire themselves to become Buddhas: this is called 'taking the *bodhisattva* vow.' Selfless service to others is part of this path; thus non-Mahayana Buddhists are said to be following the 'Hinayana' or Lesser Way. Great stress is laid on the Buddha's doctrine of 'skill in means,' i.e., adapting the teaching to the level of the hearers. This, together with the philosophical teaching of the essential 'emptiness' of all worldly phenomena, acted as a charter for developing new forms of ritual to attract lay Buddhists and non-Buddhists onto the path. These doctrines also served to legitimate the relaxation of some monastic rules, e.g., the ban on monks' handling gold and silver.

Mahayana Buddhism did not reject the pantheon, the scriptures, or the monastic discipline of earlier Buddhism; it simply added further scriptures and objects of worship. Two of its most influential scriptures were the Lotus Sutra (Saddharma-Pundarika) and the Perfection of Wisdom (Prajna-Paramita). It was primarily in this form that Buddhism then spread to China, Tibet, Mongolia, Japan, Korea, and northern Vietnam.

Vajrayana (Tantric) Buddhism

There was a still later current that is known as Vajrayana or Tantric Buddhism. This is based on scriptures known as Tantras, which appeared in India between CE 400 and 900 primarily within Hinduism and Buddhism. (In fact, there were several successive waves of Buddhist Tantras.) These scriptures were esoteric, placed great emphasis on ritual, and used magical and antinomian symbols and practices, which, they claimed, enabled the spiritual seeker under the guidance of a guru to achieve rapid results not possible by other methods. The earlier forms of Tantric Buddhism spread to China and Japan (and are still carried on in Japan by the Tendai and Shingon sects). Later forms of Tantrism, once found from India to China, survive today only as part of Tibetan and Nepalese (Newar) Buddhist traditions. The latest Tantric Buddhist scripture, the Kalachakra, can be dated to the early eleventh century and, very unusually, contains numerous references to Islam.

The development of Tantric (Vajrayana) Buddhism encouraged the emergence of Buddhist priests, that is to say, full-time ritual specialists devoted to the religious needs of lay people, who are frequently married and pass on their position to their sons. Such specialists are found in Tibet, Nepal, and Japan. The ideology of Tantric Buddhism attaches paramount importance

to the guru. He is frequently included alongside the Three Jewels of Buddhism or identified with the Buddha himself. In order to receive the full Tantric teachings it is necessary to take special initiations (Skt. *diksa*); celibacy is not a prerequisite; in fact, given the sexual nature of much of the symbolism and some of the practices, it may be an impediment. Thus Tantric Buddhism introduced a criterion of spiritual hierarchy that was sometimes in conflict with the monk/lay distinction, and at the very least served to undermine it. The necessity of a guru introduced a clear rationale for hierarchy among clerics. However, Tantric Buddhism, just like Mahayana Buddhism before it, did not reject what had gone before, but rather added to it; Tantric Buddhism therefore became the esoteric heart of a highly complex and layered set of traditions. Different schools and teachers disagreed on what exact place to give it. Monastic practice continued to be important in most forms of Buddhism. Tantrism has often been interpreted as a 'tribal,' peripheral, or 'shamanic' form of religion: however, whatever its origins, within Buddhism Tantrism was a highly sophisticated, learned, and scholastic tradition that attempted to tap some of the power of popular practices, both for salvation and for worldly benefits, while maintaining an elite distance from them.

Later Developments

In East Asia whole sects of Mahayana Buddhism grew up devoted to a particular scripture, a development that did not occur in India or Tibet. Thus, in Japan there are several sects whose primary allegiance is to the Lotus Sutra, practicing a devotional Buddhism, while others, e.g., the Shingon, have as their core practice the Tantric ritual of fire sacrifice, and yet others (the various Zen sects) focus on meditation. However, the Tendai attempts to teach and combine all the scriptures, while holding the Lotus Sutra to be the final and highest truth. In Japan, until the Meiji restoration, most Buddhist practitioners were celibate, except those of the Jodo Shinshu, founded by Shinran (1173–1263). This was one of the most radical sects focused on the worship of Amida, the Buddha of the Western paradise (Pure Land): simply uttering obeisance to Amida was all that was required for salvation; all other rules (including celibacy) were beside the point. A strong opponent of Shinran was Nichiren (1222–82), who advocated exclusive devotion to the Lotus Sutra and mounted vituperative attacks on Buddhists who did not agree with him.

In Tibet yet another innovation, dating from the thirteenth century, was the institution of reincarnate lamas (teachers), of whom the most famous is the Dalai Lama. The first Dalai Lama lived in the sixteenth century; the present Dalai Lama is the fourteenth. When a Dalai Lama dies, after the interbirth period, his successor is sought according to the indications of the state oracle. The boy chosen is believed to be both the reincarnation of the previous Dalai Lama and of the *bodhisattva* Avalokiteshvara, the special protector of Tibet. There are many other reincarnate lamas throughout Tibet and in neighboring areas where Tibetan Buddhism is practiced.

The Contemporary Situation

Currently, Theravada Buddhism is practiced in Burma, Thailand, Laos, Cambodia, and Sri Lanka. Tibet was and is a stronghold of both Mahayana and Vajrayana Buddhism, with both married and celibate practitioners. Chinese Buddhism was predominantly non-Tantric Mahayana of various sorts, as are Korean and Vietnamese Buddhism. In East Asia generally different sects grew up on the basis of different Mahayana scriptures; thus, in Japan there are both Tantric (Shingon, Tendai) and non-Tantric Mahayana schools, and even a tiny school (the Ritsu) based entirely on the practice of the monastic code. Thus when new religious movements arose in this century in Japan, naturally some were strongly Buddhist: some, like Soka Gakkai and Reiyukai, have spread through missionary activity to many different countries. The Tibetan diaspora has carried Tibetan Buddhism around the globe as well, and Theravada Buddhists have also proselytized widely. There have also been attempts to build a global ecumenical Buddhist movement, though it will prove difficult to decide who should lead it.

There is a striking contrast between the Theravada countries plus Tibet, where Buddhism became the dominant cultural tradition and came eventually to define a nationality, and East Asia, where Buddhism, though at periods dominant and favored by the elite, never achieved unquestioned acceptance. In China, Japan, and Korea the influence of Confucianism and Daoism meant that Buddhists often had to defend celibacy against the argument that it undermined society; by contrast, the spiritual value of avoiding marriage and reproduction is rarely questioned in South Asia and Buddhist Southeast Asia.

Buddhism and Political Authority

Although a minority of the first generations of monks chose to wander for 9 months of the year, most later monks and nuns settled in monasteries, working at preserving the scriptures and serving the laity. Buddhist monasteries rapidly acquired economic assets, and some were wealthy, owning villages, buying and selling land, and involved in trade. Property brought problems, requiring managers, both lay and monastic (in Theravada Buddhism monks are not supposed to handle money). On the other hand, monks and nuns are obliged to act as 'a field of merit' and accept whatever the laity offers them. Moreover, Theravada Buddhist monks are exempt from military service (in Mahayana countries, the government can make them disrobe temporarily for that purpose). Inevitably, this has often led to the suspicion that many are only interested in a comfortable and secure life, free from labor in the fields.

A king was meant to be the foremost layman of the kingdom and ensure the purity and safety of the Sangha. All ordinations took place under his authority. Following the example of Ashoka, kings were supposed to expel monks who broke the rules or fomented splits within the Sangha. It has been argued by Samuel (1993) that it was the relative strength of the monarchy in Southeast Asia that enabled Theravada to remain dominant and prevented other sects, based on the Mahayana scriptures, for example, from becoming established. By contrast, in Tibet the effective political control of Lhasa never spread far beyond the heartland, thus enabling a rich variety of Buddhist philosophies and schools to

flourish, including many that gave a much greater emphasis than the dominant Gelukpa sect to shamanic and noncelibate practice.

Buddhist kings were faced with the problem that simply in order to carry out their duty as a king – protecting the people, maintaining order – they had to commit sins (primarily killing) and were therefore disbarred from attaining salvation. At the same time, in both Theravada and Mahayana countries, the king is often regarded as a *bodhisattva* (Buddha-to-be). Ashoka is remembered as having killed many enemies in the war of Kalinga; then, after conversion, he became full of remorse and vowed not to do it again. But in Sri Lanka the heroes of the Sinhalese chronicles (composed by monks) are kings Duttha-gamani (101–77 BCE) and Parakkamabahu I (1153–86), who fought on behalf of Buddhism. The Sangha offered a way out: earning merit to counterbalance their sins though supporting the Sangha. At the same time, one of the most popular and (for Buddhists) most poignant Jataka (Rebirth) stories tells how heir apparent Prince Vessantara (the Buddha in a previous life) renounced and gave away, not only his kingdom and wealth, but his wife and children as well.

In short, the Sangha enabled the king to legitimate himself in the eyes of the people, and it refused to ordain fugitives from royal justice. In return, the king supported the Sangha, granting it land and other privileges, and when necessary carried out purifications, suppressed noncanonical innovations, and supported revivals. Only in Tibet did the Sangha eventually take over and *become* the state.

Religious Specialists and the Laity

Lay Buddhists take the Five Precepts: undertakings not to take life, not to steal, not to commit sexual wrongdoing, not to lie, and not to take intoxicants, which lead to carelessness and the breaking of the other four precepts. At fixed points in the lunar fortnight lay people take the Eight Precepts: this includes the Five (while interpreting the third to mean a complete cessation of sexual activity), and adds three others: not to eat after midday, not to adorn oneself or go to entertainments, and not to use luxurious beds (i.e., to sleep on the floor). In this way lay people, mostly women, take up the same discipline as a monastic novice, but on a temporary basis.

Traditionally, the Buddhist laity have never had to foreswear all other religious relationships. Providing they approach the gods merely for worldly matters, this is usually of no concern to the monks, and has nothing to do with their faith in Buddhism as a path to salvation. It is hard for Buddhist laity to continue to practice animal sacrifice, but even this is done by some Buddhists in Tibet, Nepal, and Thailand in what they define as non-Buddhist contexts.

The facts that Buddhism is centered so firmly on salvation and the afterlife, and that lay Buddhists almost inevitably have other, worldly interests, mean that "Buddhism in real life is *accretive*" (Gombrich, 1971: p. 49, original emphasis). Buddhism always coexists – often in a structured hierarchy that places the Buddha at the top of the pantheon – with other religious systems that satisfy the worldly needs of ordinary Buddhists. Thus, when Theravada Buddhists celebrate the harvest, seek a cure for illness, or get married, they do so in a non-Buddhist idiom with the help of non-Buddhist specialists (Tambiah, 1970). Hindu gods are included in the Buddhist pantheon as powerful spirits, subordinate to the Buddha; they traveled with Buddhism to other parts of Asia, where they were sometimes identified with local deities, all of whom became part of the Buddhist cosmology.

This soteriological focus explains why, traditionally, there is no such thing as a Buddhist wedding ceremony, although pious lay people may optionally invite a monk or monks to chant and be fed after the ceremony. Even in Mahayana countries the close relationship between Buddhism and death continues. In Japan, death ritual is almost exclusively a Buddhist concern, whereas birth and marriage are celebrated in a Shinto idiom. However, many Buddhist temples in East Asia also offer help for worldly needs; and in Nepal, among the Newars, Buddhist priests have even established a complete set of Buddhist life-cycle rituals, including marriage.

This interrelationship between Buddhism and other systems has frequently been mislabeled 'syncretism' by Western observers using an exclusivist definition of religion. But this is an ethnocentric judgment which ignores the fact that Buddhist lay people who worship non-Buddhist spirits or gods do nothing wrong, providing they do not do so in the hope of obtaining salvation. Ironically, however, modernist Buddhists have themselves adopted the Western-derived exclusivist definition of religion in their attempts to reform what they see as backwardness and superstition.

The radical individualism of the Buddha's message was socially and psychologically hard to accept. Most Buddhists, including monks, have wished to make some kind of offering to benefit their dead parents, for example. The ritualized offering of merit to others, which may include dead relatives, is common in all forms of Buddhism. In Theravada Buddhism the canonical explanation of the protective chanting ritual performed for the dead is that the dead can only benefit if they happen to be in the form of ghosts and happen to be nearby so that they can gain merit from listening. That such an abstruse justification might not be shared by all lay people can easily be imagined. In a similar way, many lay people have a straightforwardly magical attitude to the use of Buddhist amulets. Mahayana Buddhist specialists do not insist so unequivocally on maintaining a rationalist, commemorative explanation of Buddhist rituals; but they agree that the magical attitude corresponds to the lowest level of understanding.

Reforms, Revivals, and National Identity

Buddhism has always been subject to cycles of decline and reform. All forms of institutionalized Buddhism experience a tension between well-endowed institutions, which specialize in scholarship and ritual, on the one hand, and wandering or forest-dwelling monks or practitioners, on the other. Frequently, the laity (including the elite) perceive the freelance practitioners as closer to the Buddhist ideal and beat a path to their door. Over time, and thanks to the donations they cannot refuse, the freelancers themselves become well endowed, and inspire a further cycle of reform aimed at recapturing true asceticism and/or meditative practice.

The Rise of Buddhist Modernism

In the nineteenth and twentieth centuries, faced everywhere with competition from Christian missionaries and taking advantage of the new technology of the printing press, reform movements took a new and sometimes overtly political turn. Buddhist institutions experienced very different trajectories depending on the country. In Japan, Buddhism had been closely tied to the state in pre-Meiji times and Buddhist priests had been responsible for government record keeping; after 1868, Buddhism was forcibly separated from Shintoism (with mixed religious sites being forced to choose one or the other identity) and much land was expropriated (Ketelaar, 1990). In China and Tibet, Buddhism, like all autonomous civil institutions, suffered enormously under Communist rule, being permitted a limited revival in the 1980s and 1990s.

The Theravada countries have experienced a new form of rationalist, scripturalist Buddhism that has been dubbed Buddhist Modernism or Protestant Buddhism (Gombrich and Obeyesekere, 1988). In Sri Lanka this was a protest both against the Protestant missionaries and against traditional Theravada Buddhism: it criticized monks for being unlearned ritualists, for being inactive on issues of social and political concern, for not practicing meditation, and for encouraging superstition. More positively, it stood for universal literacy, Buddhist Sunday schools, and a middle-class morality of strict monogamy and hard work. It sought to base Buddhist teachings strictly on the Pali canon, and to purify practice of anything that could be dubbed Hindu or Mahayana influence. It stressed the scientific nature of Buddhist teachings, often claiming that major scientific advances were already to be found in the Pali canon. In Sri Lanka it also aimed to make Buddhists proud to be Buddhist, and to defend their cultural and religious heritage against the inroads of the Protestant missionaries who confidently predicted that in 50 years the Buddha would have gone the same way as Wodin and Thor. The rise of Protestant Buddhism went hand in hand, therefore, with the emergence of Sinhala nationalism. The Sinhalese race-nation came to be defined in terms of its Buddhism, and Buddhist historical chronicles were taken to demonstrate its long association with, and right to dominate, the island. The key figure in this Buddhist revival in Sri Lanka was Don David Hewawitarana (1864–1933), who took the title Anagarika Dharmapala, founded the Maha Bodhi Society, and campaigned ceaselessly to awaken the Sinhalese to their religious and nationalist mission.

Western Views of Buddhism and the Protestant/Catholic Parallel

The story of Buddhist revival in Sri Lanka intersects crucially with the story of the Western discovery of Buddhism. Many of the Victorians had a deep sympathy for Buddhism, because they thought it was, like Christianity, a simple and rational faith founded by a pure-hearted reformer. Edwin Arnold's poem, *The Light of Asia* (1879), had an enormous impact. Counterattacking Christian apologists dubbed Buddhism 'nihilistic' and 'antilife.' There was a pervasive tendency, which has lasted up to the present in some quarters, to view Mahayana and Theravada Buddhisms as analogous to Roman Catholicism and Protestantism within Christianity. (Hostile descriptions of Buddhism borrowed a well-worn vocabulary, honed in many Protestant descriptions of Catholicism, in which the words 'priestcraft,' 'superstition,' and 'mumbo jumbo' loomed large.) It is true that Mahayana Buddhism has a baroque pantheon, numerous elaborate rituals, and more elaborate priestly hierarchies; but the contrast was exaggerated because of the adoption of the modernist interpretation of Theravada Buddhism as a simple, rationalist philosophy whose only ritual was the commemoration of its founder. The parallel breaks down as a serious tool of analysis for several reasons:

1. Historically, Theravada Buddhism represents the earlier form, against which Mahayana rebelled;
2. Theravada Buddhism is traditionally built on monasticism, and therefore on spiritual hierarchy, and it is modernist Buddhism, which has introduced a Protestant-style belief in the equality of all believers;
3. The scriptures of the Theravada were preserved in Pali, and it is only in the modern period that they began to be translated into the vernaculars;
4. The worship of relics is very important in Theravada Buddhism, and sponsoring their worship has been an important source of legitimacy for rulers, both traditionally and in the modern period;
5. Traditionally, Theravada Buddhists believed that nirvana was impossible to attain at present, because of the degeneracy of the age, which made the quest for salvation considerably less urgent than in Protestantism.

These differences between Protestantism and actually existing Theravada Buddhism were obvious to those Westerners, such as Madame Blavatsky and Colonel Olcott, founders of the Theosophical Society, who traveled to India in search of the wisdom of the East. Olcott came to Sri Lanka in 1880 and set about reforming Buddhism, so that it could become what they claimed it had always been. It was Olcott who first set up Buddhist schools, drew up a Buddhist catechism, and encouraged the annual celebration of the Buddha's enlightenment with Buddhist carols. He was instrumental in the setting up of Buddhist Sunday schools and the Young Men's and Young Women's Buddhist Associations. He also designed the Buddhist flag, which is now flown around the world. It was Olcott and Blavatsky who first encouraged Dharmapala. Many of the early Buddhist revivalists were Theosophists as well. Dharmapala, along with D.T. Suzuki, who first popularized Zen in the West, and Vivekananda, the leader of neo-Hindu revivalism, attended the 1893 World Parliament of Religions in Chicago, a key event in the history of Buddhist modernism.

Government Control in Thailand

In Thailand, which avoided European colonialism, modernist reforms were, by contrast, largely a top–down process. The reforming King Rama IV (Mongkut) (reigned 1852–68) had spent 27 years as a monk before ascending the throne. He emphasized strict adherence to the Pali canon, excluding later, popular works that encouraged the laity to view the Buddha as a miracle worker. It was Mongkut's monastery that was the center of what was to become the Dhammayutika Nikaya, a new monastic order that stressed adherence to the Vinaya

rules. Increasing centralization led in Thailand to the Sangha Act of 1902, by which the government took effective control not just of the royal monasteries in the capital but, for the first time, of all monasteries and monks in Thailand. A national exam syllabus was established with textbooks written by Rama IV's son and the king's half brother, Prince Wachirayan, who himself became the Supreme Patriarch of the Thai Sangha in 1910. In Thailand, but not in Sri Lanka, it is the custom for all young men to spend at least 2–3 months as a monk, around the age of 20 years. (In Burma, temporary ordination tends to be taken much younger, and can last anything from a day to several years.) Giving up the status of monk and returning to lay life is not seen as in any way shameful; many men spend 10 or more years receiving an education as a monk, and then return to lay life. One consequence of tightening up of monastic education was that monasteries, which had previously had a monopoly on learning and literacy, had to stick to a more strictly religious curriculum, and many forms of knowledge – medicine, astrology, history writing – that had been passed on in them, now found a home outside.

Buddhism and National Identity

As in Sri Lanka, the reform of Buddhism in Thailand was intimately tied to the construction of a sense of national identity. Though this has now changed, Muslim and Christian minorities rarely used to be persecuted; but Buddhism receives official backing. However, the detailed government control of religion has meant that, when dissident movements arise, it is faced with the difficult choice between suppressing them in line with its traditional responsibility for the purity of Buddhism, and permitting them in the name of religious freedom.

In Burma, Thailand, and Sri Lanka the relationship between the ruling elite, the people, and Buddhism has been so close that it is possible to speak of protonationalism there even before the modern period; that is to say, the people were defined in terms of their adherence to Buddhism and any ruler who failed to protect Buddhism could not be accepted as legitimate. Certainly, when the modern period dawned and nation-states were created, it was hard to be accepted as a Burmese or a Thai unless one professed Theravada Buddhism, and many of the ethnic troubles of Sri Lanka have flowed from the fact that most Sinhalese Buddhists feel the same way. As Islam in some neighboring countries becomes more powerful and gains influence abroad, in Burma, Thailand, and Sri Lanka there is now considerable hostility toward Muslim minority communities.

There is a similarly tight connection between nationalism and Buddhism in Tibet, but in other Mahayana countries the position is very different. In Japan, Buddhism was persecuted as a foreign religion in the 1870s, and in Korea restrictions were continuous from 1392 until the twentieth century: the ruling Choson dynasty, which based itself on Confucian ideas, banned Buddhist monasteries from the major towns.

Lay Meditation and the Movement for Female Ordination

The rise of the lay meditation movement marked a major change in Buddhist practice in the twentieth century. Few monks meditated traditionally, most performed ritual services for the laity, and some studied the scriptures. The highest status went to learned monks in urban centers or to rare forest meditators. Lay life was thought to be incompatible with meditation. Part of the modernization of the religion has seen meditation being taught to the laity, often by laymen and women. For many middle-class Buddhists, this means that they bypass monasteries altogether and base their religious practice in meditation centers. Burma led the way in the development of meditation for the laity, and Vipassana (insight) meditation has spread throughout the world; for example, the efforts of an ethnic Indian born in Burma, S.N. Goenka, have been very influential well beyond the community of those born Buddhist. Zen Buddhism has perhaps been even more influential in the West, though whether the popular understanding of it accords with the way it is practiced in East Asia is open to question. In India, Bhimrao Ambedkar, leader of India's untouchables and one of the framers of India's Constitution, began a major movement of social liberation by urging his followers to embrace Buddhism and converting himself at the end of his life in 1956 (Zelliot, 1992).

Just as the Buddhist laity in general are not as submissive to monastic authority as they once were, so there has been a general movement for the emancipation of women in Buddhism. Historically, the order of nuns has always been subordinate to monks, the highest-ranking nun being considered, formally, as inferior to the most junior monk. Furthermore, within Theravada countries the nuns' ordination tradition died out in the eleventh century (Sri Lanka) and thirteenth century (Burma): since five nuns are needed to ordain a new one, the formal status of nun was no longer available to women. All that they could do was to take the Ten Precepts, like a monastic novice, on a permanent basis, and live a celibate life, a precarious and unprestigious possibility attractive mainly to widows (though often also done by elderly men). As part of the revival of Buddhism in the Theravada countries, many women started to adopt a more monastic way of life and to be treated as fully fledged nuns. In the 1980s and 1990s, Western feminist Buddhists have argued that Theravada women should take full ordination from the Chinese tradition where it has been preserved, and some have done so. This has been controversial; many of those (mainly men) who have opposed them doing so argue that they should thereby become Mahayanists or refrain from calling themselves nuns. While the theological objections are very different, the issue arouses similar passions to the ordination of women priests in the West.

'Humanistic' and 'Engaged' Buddhism

Another major strand in Buddhist modernism goes back to the Chinese monk Tai Xu (1890–1947). He founded 'humanistic Buddhism,' which emphasized better organization and a more rational outlook, in particular that Buddhism should attend to the needs of this life, not rituals for the dead. This new Buddhist tradition was renamed 'engaged Buddhism,' by the Vietnamese monk, Thich Nhat Hanh, who settled in France and America and had many Western followers.

At the end of World War II, Tai Xu and some of his chief pupils fled Maoism; though he died in Hong Kong, some

pupils reached Taiwan, which has become a major source of Buddhist revival and innovation. It is notable for having by far the highest proportion of Buddhist nuns of any country in the world; the foundation for this development was laid by the Japanese during their occupation of Taiwan between the two World Wars, after Tai Xu had played a minor role.

Two Taiwanese sects have spread worldwide in recent years. Fo Guang Shan, led by Master Hsing Yun, while relatively traditional, combines Pure Land and Zen elements, and has been active in promoting the nuns' revival overseas. Even more remarkable is Tzu Chi ('Compassion Relief'), founded and still headed by a laywoman, the Master Cheng Yen (b.1937) (who now however has an unorthodox ordination). Starting from nothing, in a remote town in eastern Taiwan, Cheng Yen in 1967 founded Tzu Chi as a medical charity; it now has six hospitals, a medical school, and the largest bone marrow bank in Asia. It also fights environmental pollution and undertakes disaster relief, notably even in mainland China. At the outset, most of Tzu Chi's members were women, who sustained the movement by unremitting fundraising; now that it has spread overseas (claiming 10 million members), probably half of the members are men, not necessarily Buddhists. Tzu Chi's vision of Buddhism is starkly simple: neither meditation nor doctrine plays any significant role; the emphasis is wholly on doing practical good, for which Tzu Chi refuses to work through any intermediary organization: every gift must be made by a Tzu Chi volunteer in person.

Budgeting and Anticipatory Management

Michel J Lebas, HEC School of Management, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Budgeting is a deliberate act of anticipatory interactive coordination of the use of a business' resources to take it in a strategically selected direction. This article describes the purposes and the principles of anticipatory management. It emphasizes the collaborative nature of this process around a shared and adaptive causal model. It asserts that practice and principles are often not aligned, thus delegitimizing the budgeting process. The author concludes by evoking the paths currently carried out so as to reinvent a relevant budgeting process and lists 10 key points any business must address to anticipate effectively and support quality strategy implementation.

Budgeting is a deliberate act of anticipatory interactive coordination of the use of an organization's resources to take the firm in a selected direction. It involves several actors in a business process in identifying alternative action plans leading to the achievement of the goal or intent, selecting one, and documenting it. An action plan allows a balancing of resources required and available or to be created. The 'best' plan (the one retained) has high probability of achieving success and has a compatible resource requirement. A budget defines (1) financial and nonfinancial measures of both outcome and intermediate milestones describing the path to success and (2) the resources required or generated by this plan.

Deviations (actual or forecasted) from the milestones are sources of learning. They are used to adapt the action plan to newly forecasted conditions so that the revised plan will remain coherent with the intent or the goal in the changing competitive environment. Traditional confusion between (1) anticipation (i.e., action plan selection and forecasting outcome and resources), (2) resource allocation to responsibility centers, and (3) the use of milestones of achievement as bases of reward systems often leads to dysfunctional behavior such as budget slack or inability to exploit new opportunities. The budgeting process serves to focus the persons in any organization on both the 'performance gap' (more and better effectiveness and efficiency) and the 'opportunity gap' (preparing the organization to handle future opportunities).

All organizations must:

1. coordinate the way resources will be used by the various (often specialized) decision-makers; and
2. learn from the observed deviations between intended and actual.

They need these two activities in order to create value for their stockholders by increasing the probability of satisfying their key stakeholders such as customers, employees, suppliers, and any outside agency granting the organization the right to continue to operate.

For the past 100 years or more, budgets have been the prime instrument in providing such a process of *ex ante* coordination and *ex post* analysis. They did so by defining, too often from 'above' (the leadership sends a 'command') in a complex and cumbersome process, the actions (and the resources attached) that are likely to lead to goal achievement, combined with *ex post* evaluation of variances or deviations from plan ('control' to bring conformance).

A budget is generally defined as a formal document that quantifies an organization's plan for achieving its goal (Jiambalvo, 2012). A budget, in other words, is a description of the financial implications of a sequence of coordinated actions and specialized targets that will allow an organization to achieve its objectives in a changing environment. Most budgets, until recently, assumed implicitly, once the budget had been defined – i.e., the actions (including resources attached) and targets selected – that uncertainties about the environment could essentially be 'ignored' for a period of implementation. Managers were expected to 'manage to the budget' more than to pay attention to the competitive environment and to new opportunities. The budget period used to be about 12 months and was supplemented by frequent updates (two or three times a year, depending on the turbulence of the competitive environment) but within the same old 12-month framework and, too often without changing the 'end of year' objectives. Despite these updates, many managers still try to 'achieve the budget,' thus still assuming an estimate, made some 6–18 months before, is still valid.

A budget is in itself a fundamental document, and budgeting is an essential process in the operation of any organization, however the way it has been used in practice has led to many abuses and negative effects.

This short article will define the principles of budgeting and 'budgets' before showing the limitations of current practice and will explore how the 'concept' (i.e., a tool to support ongoing adaptive anticipation or anticipatory management) ought to be used today to meet current economic and competitive challenges.

A Philosophy of Anticipation

"As for the future, your task is not to foresee it, but to enable it" (Antoine de Saint Exupery in *Le Petit Prince*) and, to do so means to be able to mobilize, continuously, all resources in the organization to adapt to and exploit new opportunities that appear. This means the path to 'success' cannot be completely defined beforehand.

The whole organization, and especially its management team collectively, must continuously update the 'best' way to

create value for stakeholders in continuously adapting to the competitive environment. Despite such an observation, 'command and control' are still the most commonly used form of management, essentially in contradiction to the reactivity and agility required for success in a competitive world.

Budgets and the budgeting activity (process of establishing and validating action plans) are processes and procedures that aim at contributing to the creation of value. A budget is a statement – a declaration – of actions intended to be carried out by several organizational decision-makers in a coordinated way. A budget reflects the answers a firm and its leadership give at one point in time (and it may possibly be a valid answer, but only for a short period of time) to one key question: 'How are we going to go from where we are to where we want to be?.' A budget and budgeting process is one of the key ways through which energies are mobilized and channeled for the successful implementation of the business strategic intent.

We will first identify the purposes and the process of creation of the budget, then the key requirements for the budget to be an effective tool that fulfills its promises, before reviewing criticisms of budget practices and formulating the key points we see developing in new interpretations of this fundamental tool of anticipation.

Purposes of Budgets and of Budgeting Processes

The budgeting process and budgets contribute to the firm's anticipation in that they:

1. Provide a forum in which the various organizational members (who do not have identical skills, experience, and expertise) can identify and share their views of opportunities and threats to the value creation process of the business.
2. Provide a locus for the construction of a shared business model (identify the key success factors and how they interact in creating a successful firm).
3. Allow senior management to discuss, select, and communicate values (to guide behavior), intent (defining what value creation or success means), and plans (coordinated sequence of interlocked actions and identification of resources created and consumed).
4. Create a forum for coordinated decision-making between actors that may otherwise act in a disconnected or centrifugal fashion that would result from their referring to different business models. For example, the sales manager might consider developing sales at a rate that might not be compatible with the action plan imagined by the manufacturing manager (who foresees difficulties in bringing the required new technology on line) or with the action plan of the financial manager (who would rather increase the dividends than finance the increase in working capital that the increased sales might require).
5. Provide for the development of transfunctional action plans describing how to achieve continuous alignment of the firm's 'behavior' with competitive pressures.
6. Identify what resources are needed at what time. Resources ought not be limited to tangible or financially measurable resources: know-how, intellectual capital, customer, supplier or employee loyalty, morale, image and style, etc., are resources that must be used appropriately to create and maintain long-term success.
7. Allow for the identification and allocation of the scarce resources required to carry out the action plans effectively and efficiently.
8. Reinforce a structure of delegation, devolution, and 'subsidiarity' in colocating 'rights to make decisions' (on the use of resources) and knowledge and in supporting initiative and autonomy while maintaining coordination. We use the term 'subsidiarity' to refer to the fundamental idea that decision-making should be as close as possible to the 'customer' or to the market, i.e., any unnecessary attempt at going up in the delegation chain to reach a decision is slowing down the organization's reaction and runs the risk of creating a solution which is maladapted to the need.
9. Help build commitment by individuals or groups of individuals to achieving time-based results that move the organization in the intended direction. The principle is to obtain commitment to a result and not necessarily to the way through which this result is to be achieved. This aspect is the source of great misuse of budgets in that many organizations confuse 'commitment to the use of resources as agreed upon' and 'commitment to results.' Often the source of confusion is due to a combination of lack of trust on the part of the supervisor and lack of self-confidence on the part of the subordinate.
10. Contribute to establishing benchmarks for performance measurement and evaluation (for both business units and individuals). Benchmarks need not be limited to financial measures of results or resource consumption.
11. Provide a basis for learning from deviations. This aspect has often been misunderstood to mean that conformance to the plan is expected. Since, by definition, no plan can be perfect, conformance for its own sake is a source of noncompetitiveness.
12. Create a context for the deliberate management of performance improvement.
13. Allow for the forecasting of cash flow needs on the basis of the action plans that have been retained. Cash is an essential scarce resource in any organization and must be monitored at all times.
14. Offer a process for an ongoing estimation of year-end financial results and more specifically earnings per share (EPS) and return on equity (ROE).

This whole array of purposes cannot be broken down and each aspect dealt with separately. They must all be pursued simultaneously.

The Budgeting Cycle

Generally, the budgeting process, once a strategy (direction) has been selected (by senior management), follows a preestablished sequence but many variations are possible with today's simulation instruments:

1. Identify and communicate estimated future demand, markets conditions, and business environment evolution to

establish, for every participant, the hypotheses all should assume in researching their contribution to the action plans implementing the strategy. Such a task should, most of the time, originate with upper management that holds a bird's-eye view of the whole business.
2. Jointly identify threats, opportunities, weaknesses, and strengths of the organization in the perceived (or declared) future environment.
3. Identify and evaluate the various possible action plans (sales, production, sourcing, human resources, innovation and investments, R&D, etc.) and verify their compatibility with both intent or goals and resources.
4. Repeat the process until compatibility is obtained and acceptance by everyone in the organization has been secured. This step may require the superior to act as a binding arbitrator to avoid subordinates wasting time in useless battles. An arbitrator listens to all parties, reflects on the best collective solution, and selects a preferred course of action that is both explained and justified to all parties who must adhere to it.
5. Once the budget or action plan is established, results are matched against expected (intermediate or final) milestone results and the analysis of differences (deviations or variances) leads to continuous learning and thus to a reevaluation of the appropriateness of the action plan and its possible updating.

Components of an Action Plan

An action plan reflects the answers of the concerned persons to at least the following questions:

1. Where are we and why do we need to do 'something' (understand the cause of the action plan by identifying a possible gap between where we are and where we are headed, and where we think we ought to be, given the intent or goals of the firm or organization)?
2. What is the 'intention' behind doing something?
3. How does whatever action that is decided relate to the firm's goal, target, or mission?
4. Who are the various actors who need to be involved (basis for both richness of analysis and delegation in the implementation process)? An action plan is always teamwork, even though each person on the team is personally responsible for one 'component' of the plan, often overlapping with someone else's. For example, an action plan aimed at 'generating orders that the firm can deliver to the customer's satisfaction and that help the firm grow' would require the cooperation of such specialized managers as: sales manager, sales people, marketing manager, production scheduling, assembly manager, legal department, sourcing manager, management accountant, etc. If the plan is not the result of an agreement between all these required skill holders, it has little chance of success.
5. What business model (i.e., causal model) do the 'team members' agree on to help them identify the 'action variables' they will activate through their decisions and behavior?
6. What possible actions can be envisioned? It is important to review several possible alternatives critically.
7. Which alternative will we choose, and why? What will we actually do in this action plan in each responsibility center?
8. How will we do it? What processes? What resources will be consumed and created and when? What delegation structure will be developed, etc.?
9. Are the required and generated resources coherent with the availability and needs of the organization? If the answer is negative, there must be a return for adjustment to any or all questions (1) through (8).
10. Why will we do it this way? What were the alternatives' pros and cons? How realistic is the alternative selected and how realistic were the other ones? What are the risks attached to each alternative and especially the one selected?
11. Coherence with strategic intent, strategy, and other action plans.
12. Expected impact of the selected actions (several may apply simultaneously):
    a. development of a competitive advantage;
    b. ambitious yet realistic: placing the organization under tension;
    c. challenging existing ways of thinking; and
    d. all of the above or other.
13. When will these actions be carried out (calendar of actions)?
14. How often will these actions need to be carried out (if plan requires recurring actions)? A multistage and conditional action plan allows for better learning and facilitates continuous adjustment.
15. To what do each of the actors actually commit: milestones, dates, intermediate or final results, nonfinancial indicators, relationships, etc.?
16. How will the achievement of the commitments be measured? There are at least three domains for which measures should be agreed upon beforehand by all parties involved in the action plan. These measures will serve as a basis for learning from deviations and for continuously updating the action plan so that it remains aligned with the intention selected, if it is still the right one:
    a. Process, i.e., the way the action plan should and does unfold during implementation (the equivalent aerospace term would be 'trajectory'):
        – evolution of the conditions that created the need for the action;
        – resources consumed and created;
        – resource productivity and effectiveness;
        – organization and relationships between actors;
        – mastery over risks identified in step (10);
        – efficiency of use of resources; etc.
    b. Progress (against the time scale selected by the actors in the plan to state by which date the target will be achieved):
        – timing: date of start, selection of milestones, date of expected completion;
        – positioning of progress on a PERT diagram (Program Evaluation and Review Technique, a tool used in project management that creates a dynamic

map the sequence of actions required to completion and records duration – theoretical and actual – and defines a critical path) or other time-based diagram(s);
  - validation of the critical path;
  - definition of the method of calculation of the percentage achievement; etc.
c. Impact:
  - effect of actions on objectives and key performance indicators (KPIs) for both short- and long-term; and
  - evaluation of the continued relevance of the intent.

17. What priority should be given to this action plan and how much of the firm will be involved (if applicable)?

During the twentieth century budgeting seems to have focused essentially on steps (8) and (9) and therefore has led to a very partial view of what is meant by an action plan. Essential to the effectiveness of the budgeting process is the measurement system evoked in step (16). The measures should be balanced between areas of expertise, perspectives, and time horizons and allow both effective implementation and continuous validation of the relevance of the whole action plan given the evolution of the competitive environment. Budgeting and processes of anticipation link, therefore, directly to the area of management now commonly described as the Balanced Score Card.

Budget Process Requirements

A Sense of Direction

There must be goals that preexist the beginning of the budgeting process. Each goal must have a time frame and be a milestone toward achieving the organization's mission or intent. In specifying its goals, the organization states which are the stakeholders that are taken into consideration.

A Continuously Updated Shared Causal Model

Decision-makers and personnel must be able to understand some key 'cause and effect' relationships that affect the organization's output or performance. The budget rests on the identification of a causal model that helps understand what consequences might result from what actions in the perceived competitive environment. Much time is needed in a business to identify and maintain the model(s) or causal representations that will help understand how it could go from point X to point Y on the map of opportunities.

A Monitoring System

A monitoring system must be able to tell managers how well they are 'getting there' from 'here.' Some of the measures must be anticipatory or 'leading,' in the sense that they allow the managers to anticipate inappropriate or unacceptable results and therefore head off the undesired trend through appropriate corrective actions, while other measures are more historical and serve to keep track of what has been achieved.

A Set of Criteria for Trade-Off Between Goal Achievement and Resource Consumption and Creation

Whether the trade-off will be carried out in economic terms only or using criteria such as market share, employee satisfaction, or citizenship of the firm, the firm needs to have some preference ordering system that allows it to identify a 'preferred way' each time a choice is to be made. It is very difficult in any multi-person setting to come to an agreement on criteria for preference ordering. The budgeting process allows managers to encourage participation and expression on the part of everyone in the organization and communicates values and preference orientations.

A Budget Requires Trust Between Participants

A budget is grounded in delegation. Each person holds responsibility for a 'piece of the action' and must be able to count on the others doing what they committed to do and letting their partners, who depend on the achievement of a milestone or of a result, know as early as feasible (through shared leading indicators) the actual changes in the probability of fulfilling the commitments. Budgets therefore require trust between participants (both vertically and laterally) and self-confidence combined with a reasonable willingness to take risks and not adhere to a prewritten script.

Budgets, 'Opportunity Gap,' and 'Performance Gap'

In projecting itself into the future, any organization faces two simultaneous challenges:

1. Improve the 'productivity' (effectiveness and efficiency) of resources consumed in carrying out currently retained action plans.
2. Identify new opportunities for continued growth that may require modification of current action plans and, possibly, the development of entirely new ones. Opportunities have a limited life span. If no new opportunities are identified and addressed, the organization will cease to grow and decline into oblivion. Single-purpose organizations have had to reorganize their mission completely to continue existing. For example, the March of Dimes, founded in 1938 by President F.D. Roosevelt to fight polio, shifted its mission to the prevention of premature birth and birth defects; the Tennessee Valley Authority, founded in 1933 initially to transform an agrarian region through the use of electricity is now mainly an interstate regional economic development agency. A long-lasting organization such as the Kirin Beer Brewery (incorporated in 1907) or Coca-Cola (formulated in 1888, incorporated in 1892) are always reinventing themselves because product attractiveness has a time limit and markets have limits.

We define the first challenge as that of managing the 'efficiency and effectiveness gap' while we will call the second one that of managing the 'opportunity gap.' As business environments grow turbulent, the continued relevance of any given action plan in delivering effectiveness is less and less likely.

Figure 1 Continuum of turbulence in the environment.

Simultaneously, the need for continuous identification of new opportunities grows greater.

Figure 1 shows that, at any point in the continuum of turbulence, the required anticipation thought processes of an organization results from the combination of both 'managing the efficiency and effectiveness gap' and 'managing the opportunity' gap (preparing the organization for the future). At each point on this continuum, managers must hold simultaneously two very different mental maps, in differing proportions.

The effectiveness of the budgeting system regardless of the level of turbulence (i.e., competitive environment) requires that managers and supporting processes take into account the appropriate mix of attention paid to both the efficiency and effectiveness gap and to the opportunity gap.

Competitive turbulence affects each level of delegated responsibility differently in the organization. It is the responsibility of a superior to 'filter' some of the uncertainties and turbulence he/she faces for his/her subordinate.

The higher the person is in an organization, the higher the degree of uncertainty he/she has to deal with. Therefore, the higher the person is, the more his/her anticipation efforts should be dedicated to addressing the 'opportunity gap,' but addressing some form of efficiency and effectiveness gap cannot be delegated entirely. As responsibility is delegated down the organization, each successive level is more and more focused on the efficiency and effectiveness of the organization, but there is always a nonnegligible preoccupation with some form of attention paid to the opportunity gap, recognizing that new opportunities can be identified at all levels of the organization.

Current Budgeting Practice is not Always Aligned with the Principles

As mentioned previously, it is a challenge to build a budgeting process that considers the issue of competitiveness not only from the point of view of the efficiency and effectiveness gap (resource consumption control, process efficiency, delivery of promised results, etc.) but also from that of the opportunity gap. The causes for such a difficulty can be traced to the following elements:

- Objectives and processes to get to the target are often defined only *in* and *on* financial terms.
- Value creation is mostly defined in terms of financial profit.
- Partition of the processes to achieve the target tends to be carried along hierarchical or functional lines rather than being developed along the necessarily transfunctional business processes of the customer-value creation process.
- The processes of alignment, dialog, and team building through budget construction are frequently ignored and the exercise is too often reduced to a process of scarce resource allocation leading to competitive behaviors between organizational entities that ought to cooperate to serve the stakeholders best.
- The time horizon of action plans is not linked to the business cycle but is based, too often, on fiscal year constraints (which are defined by reporting needs and have little link with the need to have visibility of the future). Budgeting should be carried out as an ongoing process, with rolling forecasts. Today's information technology makes it economically feasible. Budgeting is a state of mind. Budget construction should be reengineered in most firms to take as little time as is possible (for example, by concentrating on the relationships in the causal model and on leading descriptors of the status of these relationships). If the budget were an ongoing process, frequent debates would take place that would continuously replace the firm on the most appropriate trajectory or path to its objectives and targets, thus developing confidence and commitment on the part of all in the organization.
- Many times the budget has been hijacked as a substitute for an anticipatory form of financial accounting used in estimating year-end accounting results of the firm so that management can comfort stockholders about forecasted profit.
- Focus is more on cost reduction than cost management (the 'right' cost is not always the least cost: costs are driven by product and process design, and by people eliminating non-value-adding activities).
- Most action plans assume, usually erroneously, that costs are driven by the volume of sales and are best controlled at the point where they can be measured (Lebas, 1999). This leads to conformance budget (focused on resource allocation) thus limiting initiative and customer satisfaction.
- Many budget processes merge and confuse anticipating and defining benchmarks for reward systems (especially if the latter are based on conformance with resource consumption) thus creating gaming behavior and budget slack (budget padding) which immobilize resources uselessly. Budget slack occurs when managers overestimate resource consumption or required effort and underestimate value created with the customers. Managers indulge in such behavior because most of the time they do not trust the leadership either to make additional resources available when new opportunities arise (added to the fear of the corollary, i.e., that resources might be taken away when anticipated opportunities do not materialize) or to allocate resources in support of action plans that are compatible with the manager's perceptions. Such behaviors immobilize resources and prevent the exploitation of unforeseen opportunities. Practices such as 'flexible budgeting' are designed to address this concern. This practice consists in:
  - separating clearly, before the fact, what areas of the business model each manager is responsible for (i.e., which parameters are under his/her control) and for which results commitments are made, from those parameters that are not under the person's control, and

- recalculating, after the facts are known, the elements of the action plan (consumption of resources as well as outcome or output) that would have been determined had the 'uncontrollable' elements been forecasted with pinpoint accuracy.

Such an approach allows managers' freedom to really anticipate and forecast because he/she knows no precautions are needed (through the building of budget slack) to cover risks he/she cannot control.

- Often, the budgeting process does not implicate everyone in contributing to the definition of goals, targets, and action plans, thus preventing buy-in of the decisions made. A frequent reaction is to consider that 'spending' resources allocated for an action plan becomes the objective rather than continuously validating the alignment, with the intent, of the planned actions that led to the original allocation.

The main weaknesses of many budget processes currently in place in too many firms are that they are not built on a well thought-out system of:

1. shared representations of causal relationships between actions and consequences;
2. subsidiarity and delegation which would rest on trust in people's ability to make the right decision at the right time, as close to the point of need as possible;
3. representation of the firm as a network of business processes; and
4. customer orientation.

Conclusion

Anticipatory tools today are not constrained by the fiscal time horizon; they are rolling and cover a period often closely related to product life cycles. Anticipatory practices recognize the preeminence of the human aspect in the success of businesses. Choosing the right people and motivating them in well thought-out and coordinated processes make for satisfied customers who, in the end, drive the financials of the firm. Such a sequence requires flexibility and continuous adaptation.

On the basis of the experience of many firms that have developed anticipatory practices that are more coherent with the principles we have listed above, we can come up with a set of good practices that define anticipatory management for the twenty-first century. Such firms include Svenska Handelbanken, Volvo Cars, or Skandia in Sweden; Schlumberger, Air Liquide, or Bull Group in France; Borealis in Denmark; Statoil and SpareBank1 in Norway; Boots the Chemist in the UK; or Elkey Manufacturing, Group Health Cooperative or Sprint in the US; Tenaga Nasional in Malaysia; or Grupo Auto Sueco in Portugal. Their practices, although case-specific, can be distilled to a common set of principles, which include the following elements:

1. Release individuals' creativity and initiative by generalizing entrepreneurial centers (business units that are large enough to be profit driven, but not so large they would lose agility).
2. Develop a 'customer-oriented' model of performance creation in each business unit.
3. Develop a shared causal model described by a set of multivariate key performance indicators specific to each business unit, nested in a firm wide business model that encompasses all units.
4. Nested devolution of strategy and responsibility, within and between units.
5. Time-bound autonomy: i.e., *the right to err and correct* as described, for example, in the "Management Principles" formulated by Percy Barnevik, then CEO of ABB, in 1988).
6. Implementation, throughout the firm, of the philosophy of continuous progress, i.e., the Deming PDCA model (plan–do–check–adjust) benchmarked on competition.
7. Rigorous commitment of managers and business units to understandable and controllable balanced 'indicators' (i.e., generalized use of Balanced Score Cards).
8. Rolling Forecasts and Action Plans with flexible and case-specific time horizons.
9. Disconnection of forecasts from the commitment/reward system.
10. Resources allocated on the basis of justified need: internal 'market' for resources and transparency in allocation.

These firms have moved from a twentieth century culture of seeing budgets as a set of contractual commitments within limited resources, with an emphasis on preventing centrifugal forces, to a twenty-first century view that emphasizes doing better than the competition and encouraging autonomy of and cooperation between units. They have shown that there are alternatives to the old mechanical model. The principles we listed here are not the definitive answer to what will be a work in progress for a long time.

The fact is we are entering an era of continuous adaptation and learning. Businesses need to adapt the tools too, and the 'budget' will not be spared here. Because they have to be completely reinvented, 'budget processes' (coordinated anticipatory processes) should be even more fascinating to students, management researchers, and managers alike than they were before.

Budgeting: Political Science Aspects

Abstract

The study of public budgeting enables political scientists to theorize about the allocation of government resources, the development, structure, and dynamics of political institutions, and the formation of comparative fiscal and macroeconomic policies. Among the major theories either derived from or used to study budgeting are incrementalism, decrementalism, punctuated equilibrium, and rational choice theory.

Budgeting is a process by which governments allocate public resources to bureaucracies, other governmental units, and client groups. This process usually takes place on an annual basis, involves procedural rules and institutional arrangements, often invokes intense political conflict, and, together with taxation, forms the basis for fiscal and macroeconomic policy. Because it fundamentally determines political winners and losers through its allocative function, budgetary processes and outcomes serve as a distinct guide to a state's philosophy of government and public policy. The act of budgeting, therefore, lies at the heart of politics and government.

The Study of Budgeting

Budgeting may be studied from several perspectives. From the vantage point of professional schools of public administration, the practical elements of budgeting include the drafting and formatting of budget documents, the application of cost–benefit and other tools of program analysis, the projection of revenues and expenditures, the division of spending into its operational and capital components, and the management and implementation of programs funded through the budget. Economists principally focus on the macroeconomic consequences of budgeting, such as the effects of deficit spending on interest rates, inflation, the 'crowding out' or 'crowding in' of private investment, foreign exchange rates, and national debt management. At the microeconomic level, economists may also consider the effectiveness of specific programs funded in the budget, such as determining the influence of public jobs programs on the labor market. These questions may also be of interest to and addressed by political scientists. Yet, the centrality of political science research looks at budgeting as a guide to a broader theoretical analysis of politics, the examination of institutional arrangements, an understanding of the behavior of political actors within those institutions, and an exploration of specific public policies.

Budgeting as Incrementalism

Modern theoretical understandings of budgeting begin with the idea of 'incrementalism.' Formulated in the 1960s, incrementalism attempts to explain how budgetary actors carry out their roles, and what the consequences are for politics in structuring budgetary decisions in one form as opposed to alternative ones (Wildavsky, 1964; Fenno, 1966). Incrementalism is grounded in certain assumptions derived from social psychology about human nature. The theory contends that people are inherently limited by cognitive, time, and resource constraints from being truly rational and synoptic in their ability to make budgetary decisions. Budgetary actors 'muddle through' and 'satisfice' rather than 'optimize.' They are constrained from making decisions in the way that microeconomically rational consumers might, weighing all information sources and alternatives before a decision is reached. To compensate, these actors rely on 'aids to calculation' and institutional norms and roles to govern behavior. In particular, instead of reviewing every program and spending item in the budget to determine what should be funded, the focus of analytical and political decision making is the annual change, or increment, in spending. The budget base or the previous year's spending is taken as a given, and the politics of budgeting revolve around determining the size of incremental 'fair shares' allocated to budgetary claimants.

Incrementalism takes into account the role of institutions and actors within those institutions. Budgeting is regarded as a decentralized, 'bottom-up' process, where budget proposals emerge both from within executive branch agencies and from the demands of politically successful client groups. In the case of the United States, federal agencies serve as advocates for larger funding increments for their programs to the Appropriations Committees in the House of Representatives and the Senate. Committee members evaluate these funding claims and act according to a set of behavioral norms. The House Appropriations Committee, for example, operates as the 'guardian of the purse,' and the Senate Committee acts as a 'court of appeals.' Wildavsky and Fenno saw the appropriations process as a form of legislative oversight of the bureaucracy. Where agencies proposed ever-growing budgets to expand their administrative domain, appropriators regularly trimmed those requests to keep the bureaucracy under control. Fenno, for example, noted that agency budget requests were cut 77% of the time by the House Appropriations Committee to enforce bureaucratic discipline.

Meanwhile, new client groups gain their access to fair shares of the budget through the electoral process. These groups establish their political legitimacy and justify their budgetary claims by supporting the successful election of members of

Congress. Sympathetic and electorally beholden members then create programs that are administered by these agencies and included in the budget base. Once added to the base, client groups may then rely upon receiving annual incremental budgetary allocations.

Institutional norms also guide how committees produce fiscal coordination. The House and Senate Appropriations Committees act separately in making their spending decisions and they act independently from the revenue-generating House Ways and Means Committee and the Senate Finance Committee. Nevertheless, according to incremental theory, budgetary coordination stems from the overarching norm that budgets should be balanced. Consistent with this norm that is deeply rooted in American political history, Congress would grant spending increments just within the margin of revenue growth.

Incrementalism views budgeting, above all else, as a political activity that gives limited consideration to notions of administrative efficiency or economic rationality in the determination of budgetary outcomes. Both agencies and politicians instead rely upon incremental aids to calculation. For bureaucrats, incrementalism implies stability and long-term growth in resources. For politicians, incrementalism reduces societal tension and political conflict; because interested groups quickly learn that once their claims are included as part of the budget base, they may count on regular, and presumably, growing increments.

Challenges to Incrementalism

Critics of incrementalism soon argued that the model had become obsolete. First, alternative methods of budgeting came into vogue that directly challenged incrementalism's assumptions of limited human rationality and organizational capacity. Zero-based budgeting (ZBB) and program budgeting in the form of Planning, Program, Budgeting (PPB) were designed to improve the choices of decision makers (Schick, 1966). Supporters of ZBB declared that the entire budget, rather than just the increment, could be analyzed and evaluated in detail each year by breaking up the budget into discrete 'decision units.' Policy makers would then be given the opportunity to reprioritize and reassemble these units to make rational decisions about which elements of the budget would be funded. Defenders of PPB argued that multiyear planning, rather than annual incrementalism, enabled decision makers to set broad, strategic, programmatic goals and analyze the long-term fiscal implications of current budgetary choices. New analytical techniques and growing computer capacity contributed to the development of Baseline Budgeting, where current spending levels serve as the baseline for estimating future rates of programmatic spending, by taking into account inflation and changes in law. Thus, ZBB, PPB, and Baseline Budgeting, each in its own way, rejected the basic assumptions of incrementalism in favor of presumably more rational, analytical, synoptic, and multiyear practices that could lead to more effective decision making and more efficient government.

Second, where incrementalism depended upon budgetary growth for its conflict-reducing fair shares and growing budget bases, the rise of deficit spending, economic instability, and ideological demands for reductions in the size of the public sector caused governments to engage in 'decrementalism' rather than incrementalism. By the mid-to-late 1970s, governments confronted the politically difficult task of making decremental reductions in spending through 'cutback budgeting,' rather than by providing for orderly budgetary growth. Political scientists noted that governments throughout the world coped with fiscal stress by adapting similar techniques to control budget deficits (Schick, 1986, 1988). Budgeting became more centralized, 'top-down,' and 'front-loaded' to reduce the influence of budgetary claimants, as compared to incrementalism's bottom-up approach that assumed stability in the budget's base and ignored the executive branch in setting the budgetary agenda and shaping policy outcomes. The cuts in spending that took place in Australia, Canada, Denmark, New Zealand, and Sweden, for example, were accompanied by the top down centralization of budgetary decision making throughout the parliamentary formulation and administrative execution of the budget. Governments established macrobudgetary rules at the beginning of the budgetary process that constrained bottom-up decisions taking place during the remainder of the process; employed hard-spending targets, ceilings, and caps to limit spending; calculated long-term inflationary and program costs through baseline budgeting; created new legislative committees and support agencies to impose greater oversight on the budgetary process; strengthened the powers of finance ministers over line agency spending demands; and outsourced government functions to private contractors. Whereas incrementalism, its critics claimed, neglected to address the rise of entitlement spending, the new macrobudgetary rules imposed 'pay as you go' requirements that mandated offsetting revenues or spending cuts to pay for new entitlement programs.

Domestic and international politics often revolved around the budgetary and fiscal decisions that stemmed from new macrobudgetary rules. The United States employed a variety of formal rules in the 1980s, 1990s, and in 2011 to balance budgets, control deficits, and constrain spending (Savage, 1988; White and Wildavsky, 1989). The Balanced Budget and Emergency Control Act of 1985, better known as Gramm–Rudman–Hollings, mandated that the budget should be balanced by setting annual deficit targets over 5 years. Excessive deficits would be reduced by automatic budget cuts, called sequesters, in various categories of spending. American politicians learned they could not balance budgets in the midst of recession and expanding deficits, because the size of sequesters required, proved to be politically impossible to activate. The politicians changed their target from balancing the budget to controlling spending, and they replaced Gramm–Rudman–Hollings with the Budget Enforcement Act of 1990. This law set spending caps that would be forced by sequesters, and it imposed 'pay as you go' requirements. The Congress renewed a version of this law in 1997 and enacted the similar Budget Control Act of 2011.

The European Union (EU) created its own set of macrobudgetary rules as part of its continued efforts at political and economic integration. In 1972, the EU adopted the Treaty on European Union, also known as the Maastricht Treaty, which required that member states seeking to join the Economic and Monetary Union (EMU) bring their budget deficits within the 'reference value' of 3% of GDP and their debt within 60% of

GDP. To ensure continued compliance with these targets after member states successfully entered the monetary union, the EU adopted the Stability and Growth Pact in 1997. Despite the Pact's threat of financial sanctions, as shown in Table 1, numerous member states violated the targets, especially as the financial crisis of 2009 ravaged Europe's economy. The collective deficits of the 17 countries using the euro currency grew from 0.7% of GDP in 2007 to 6.4% in 2009, with the deficits of numerous states far exceeding this level. Deficits in all of the 27 EU countries grew from 0.9% of GDP in 2007 to 6.9% in 2009. Member states hid the true condition of their deficits to gain entry into the EMU, and then disguised their deficits to avoid the financial sanctions that could be imposed under the Pact. In response, the EU adopted additional surveillance procedures and rules that promoted deeper economic and fiscal integration in 2011 and 2012. Nevertheless, the EU avoided imposing the Pact's financial penalties on any member state for running excessive deficits, justifying the absence of sanctions on the basis that the financial crisis produced extenuating economic conditions. The EU repeatedly granted extensions to the member states, even as many of them attempted to bring their budgets into compliance, often through politically unpopular austerity programs (Savage, 2005; Hallerberg et al., 2010; Heipertz and Verdun, 2011). These measures did reduce the collective deficits in the 17 country euro area to 3.7% of GDP in 2012, and in the 27 EU countries to 4.0% of GDP.

Third, another challenge to incrementalism's assumption of ongoing budgetary stability came from punctuated equilibrium theory. Where incremental theory predicted stable, fair share budgetary allocations, competing analyses of long-term, cross-national spending patterns reveals a combination of incrementalism mixed with dramatically large changes in expenditures. These large-scale punctuations of the status quo stemmed from radical and urgent changes in public priorities and policies (Jones et al., 2009). As a result, from time to time, budgets experienced 'bursts of spending,' or, less likely, reductions in spending. After responding to these policy changes, spending reverted to long-term patterns more consistent with incrementalism. Although it does not account for these substantial variations in spending, incremental theory does note the presence of 'shift points' in expenditure patterns and deviant cases due to changes in public policy.

Table 1 European Union Euro Area Government surplus/deficits (−) as percent of GDP, 2007–2012

Rational Choice Approaches to Budgeting

Since the early 1980s, many political scientists have come to rely upon economically inspired rational choice models, rather than incrementalism's social–psychological approach, to study budgeting. The basic assumption of rational choice is that political actors rationally seek to maximize their self-interest. Holding power is central to political self-interest and in democratically elected governments this means gaining reelection. Consequently, political institutions and public policies, including budgetary processes and outcomes, are structured by politicians for electoral purposes.

Symptomatic of reelection budgeting is distributive 'pork barrel' spending, where members direct appropriations to their states and districts to win political credit with their constituents. Pork barrel projects are also allocated as side payments to create coalitions of legislators in sufficient numbers to pass legislation. Depending upon the model, the size of these coalitions vary from 'minimum winning coalitions' that contain a majority plus one legislator, to 'universal coalitions,' where all legislators who seek a project receive one. The budget is therefore characterized by programs where projects are provided for each legislative district. As a result of distributive spending, the government expends funds on economically dubious projects that create large, systemic budget deficits, with what are presumed to be negative consequences for the macroeconomy (Shepsle and Weingast, 1981).

Like incrementalism, the basic rational choice model has not gone unchallenged. Although politicians do engage in distributive spending, the cost of these projects is insufficient to account for the huge budget deficits that occurred in the 1980s and 1990s. Entitlement spending, principally in the form of pensions and health care expenditures, rather than pork barrel spending, is clearly the primary source of budgetary growth. The rise of large-scale deficit spending in the United States, moreover, may also be traced to stagflation, recession, monetary policy, tax cuts, and the buildup in defense spending during the 1980s. Furthermore, politicians in many countries have risked their own reelection chances by pursuing politically costly fiscal policies, including cutbacks in distributive spending, in order to reduce these deficits.

The minimum winning and universal coalition elements of the rational choice models, which have often been expressed in formal, mathematical terms, have also been challenged on empirical grounds. Individual discretionary government projects appear to benefit only a limited number of legislative districts. Even when bundled together for purposes of creating voting coalitions, most program portfolios fail to provide universal benefits for all districts. While the rational model assumes that pork barrel budgeting takes place for reelection purposes, individual constituents overwhelmingly receive their

government benefits from entitlement and general benefit programs, and not from the lower-visibility, pork barrel funding (Stein and Bickers, 1995).

Institutions, Divided Government, and Budgeting

Studies suggest that divided governments, where competing political parties control the executive and legislative branches, experience greater difficulties in controlling budget deficits and expenditures than unified ones (Alesina and Rosenthal, 1995). Leftist parties spend more than rightist parties, and parties differ in their spending priorities. Changes in the American budgetary process since 1974 enhanced the power of the parties to set overall budget and fiscal priorities, though the detailed spending decisions remain the prerogative of the committee system. When control of the government is divided, priorities conflict and fiscal stalemate is likely to occur. Similarly, the more unified and conservative the government, the greater the priority to balance the budget (Kieweit and McCubbins, 1991).

Incrementalists add that a divided government also influences the advocate and guardian roles of budget makers. Whereas the early incremental models regarded specific roles as enduring, the behavior of budgetary actors during the rise of divided government indicated they were in fact mutable (Cox et al., 1993). When rightist parties control the executive branch, for example, the executive becomes less of an advocate of spending and more of a guardian or protector against perceived budgetary excesses. The more leftist-oriented the House Appropriations Committee becomes, the less its emphasis on guardianship, particularly in the presence of a conservative executive. A decreasing level of guardianship is associated with the growing size of deficits. The Senate Appropriations Committee, meanwhile, tends to remain in its role as a court of budgetary appeals.

Budgeting, Foreign Assistance, and State Building

Budgeting plays a role in international relations and political development. Democratic budgetary institutions and processes are regarded as key contributors to good governance, the rule of law, democratic deliberation, transparency in public affairs, political accountability, and the efficient provision of public services. The failure to budget effectively, on the other hand, contributes to dysfunctional government. Dysfunctional governments, especially those falling into the category of failed states, pose a potential threat to other states due to their tendencies toward political instability, unrest, and violence. Consequently, recent theories of political development and state building point to the need to provide foreign assistance and technical aid to promote state budget capacity, in order to encourage democratic development and economic growth, and to reduce international conflict in developing and post-conflict countries, including Afghanistan and Iraq (Ghani and Lockhart, 2008; Savage, 2013).

International organizations, donors, and national development agencies have indeed provided technical assistance to build state capacity in all the phases of budget formulation, adoption, and execution. Budget formulation refers to a government's technical ability to draft credible budgets that reflect coherent and detailed programmatic spending plans. Budget adoption refers to a government's political ability to evaluate and pass a budget in a deliberative manner. Budget execution refers to a government's administrative ability to spend the funds allocated in the budget effectively, honestly, and in a timely fashion consistent with international best practices.

Foreign assistance and democratic development projects, however, have experienced mixed success. Critics note the failure of international organizations and donors to coordinate their own assistance efforts, provide adequate oversight in the use of development funds, and offer adequate training of beneficiary personnel, to name just some of the limitations of these interventions. As a result, the beneficiary governments remain in a failed and dysfunctional condition, plagued by instability, violence, and corruption (Collier, 2008). In this regard, one ongoing debate is whether foreign assistance funds should be spent directly, 'off-budget' by the donors, or transferred to and spent 'on-budget' by the beneficiary governments. Donors often prefer to spend their funds directly through their own budgets to ensure that their project preferences are maximized and the mismanagement of their funds are minimized. Doing so, however, delegitimizes the beneficiary government, conflicts with state spending priorities, encourages governments to remain dependent on donor funding, and undermines efforts at building political accountability for government actions (del Castillo, 2008).

Budgeting and Political Science

Incrementalism and rational choice-based theories have greatly contributed to political science's analyses of the politics and the institutional forces that create budgets. These models and theories and the challenges presented to them offer important policy implications for budgeting. Incrementalism points to the norm of budget balance as a reoccurring goal of public policy. Challenges to incrementalism point to new procedures and rules to improve budgetary decisions. Rational choice accounts for the presence of often wasteful distributive spending that threatens the success of government programs and public policy. Political scientists have also studied budgeting in the context of international relations, comparative politics, and political development. The evolution of non-incremental budgeting macrobudgetary rules plays a central role in European integration. Budgeting is also seen as an essential factor in the development of good governance and effective administration for developing and postconflict countries.

Abstract

Swiss historian of art and culture, in conscious contrast to the contemporary professionalization of historical science he retained an older, personal understanding of learning and education. Historical education should not contribute to an alteration of the outer reality, but widen the mental horizon of those seeking knowledge. With this maxim, his independent cultural historical method, and his art of portrayal not only in fact influenced the educational horizon of those interested in history to a great degree, but also had a stimulating effect on the increasingly specialized areas of historical science (ancient history, modern history, history of art).

Jacob Burckhardt was born in Basle, Switzerland on 25 February 1818 as the son of the pastor of Basle cathedral. At first he studied theology in Basle, although after a religious crisis he changed to history and history of art, and continued his studies in Bonn and Berlin from 1841 to 1843. He was most influenced, especially in Berlin, by Franz Kugler, Johann Gustav Droysen, August Boeckh, and Leopold Ranke. He habilitated at Basle in 1844, held lectures in history and history of art there, and edited the 'Basler Zeitung' from 1843 to 1845. After the uprisings in Switzerland of 1844–45, an early manifestation of the midcentury revolutionary unrest in Europe, his previously liberal political outlook changed into a decided conservatism. With this he turned away from his political and publishing activities in favor of the 'education of old Europe.' In 1855 he was appointed to a chair at the technical university of Zurich, and in 1858 at Basle, where he taught history until 1886, and history of art from 1874 to 1893. In 1860 he stopped publishing and concentrated on his lectures, although he completed a number of manuscripts after this point. He died in Basle on 8 August 1897.

Jacob Burckhardt's historical writing can be understood as a critical diagnosis of the present. This found its most clear expression in his lectures on the history of the revolutionary era and *Über das Studium der Geschichte* (*On the Study of History*) as well as in references to the present throughout his work. Burckhardt rejected the liberal historians' optimism in progress, and saw a danger for his ideal of culture in the contemporary processes of mechanization, industrialization, and fundamental democratization. He also felt the modern development of large states to be a threat, particularly that of the new German Reich from 1871, and he made accurate prognoses of the political catastrophes of the twentieth century. However, his historical pessimism was in contradiction at least to his early religiously influenced opinions on and admiration of art. In numerous long tours through Italy he worked on the basis of his extensive works on art history, and these journeys through Italy, France, and The Netherlands remained an important part of his life until his old age. In 1855 he published *Cicerone. Eine Anleitung zum Genuß der Kunstwerke Italiens* (*Cicerone. An Introduction to Enjoying Italy's Art*), a work which visitors to Italy interested in art still use today. In 1867 his work, *Kunst der Renaissance* (*Art of the Renaissance*), was brought out by his friend Wilhelm Lübke. In this work he deliberately avoided a history of the artists themselves and instead concentrated on a 'history of art according to functions.' His late masterpiece *Erinnerungen an Rubens* (*Memories of Rubens*) was published from his papers after his death, in which the re-evaluation of the Baroque which he had completed in his later years found its expression. His portrayal of Renaissance art had an important influence on the educated German public's reception of the Renaissance and Italy. With his concept of a history of art ordered according to functions he guided the emerging study of art on to new methodological paths.

Burckhardt's basic historiographical principles are most clearly illustrated in his introductory lecture *On the Study of History*, which he held three times between 1868 and 1873, and which his nephew Jacob Oeri edited and published in 1905 under the now famous title *Welthistorische Betrachtungen* (*Reflections on History*). Burckhardt drew up his images of the historical world from a universal historical perspective, assuming three basic human needs: (1) the political (state), (2) the 'metaphysical' (religion), and the 'critical' (culture). In this scheme of 'potencies' he relativized the importance of the nation and the nation state in conscious contrast to German historicism, and allotted an equally important role to culture as the expression of human spontaneity as to the 'stable' powers of state and religion. As culture he understood 'the quintessence of all that which has come into existence spontaneously for the promotion of material life, and as the expression of the spiritual and emotional–traditional life, all social gathering, all technologies, arts, writing and sciences.' Burckhardt thereby rediscovered an enlightenment tradition of cultural history, and consolidated it in that he saw the polarity of freedom and violence in a developed form not only in state and religion, but also in culture. However, the potencies theory also enabled him to relativize the stress on a typological basis. The interaction of the three potencies adds depth and complexity to historical reality, as Burckhardt experienced it.

In his three historical masterpieces, *Die Zeit Constantins des Großen* (*The Age of Constantine*), (1853), *Die Kultur der Renaissance in Italien* (*The Civilisation of the Renaissance in Italy*) (1860) and *Die griechische Kulturgeschichte* (*The Cultural History of Greece*) (*3 volumes, 1898–1900*) Burckhardt varied the potencies scheme in that he added a further definition of

culture to state and religion. Culture is then the entirety of the achievements of a human creative urge, which is, however, permanently under threat of being destroyed. In all three works Burckhardt assumes a state of acute breakdown of authority and an increased societal and moral antagonism. In this latent chaos the respective forms of state and religion represent the relatively stable potencies, which, however, remain fragile because the 'spirit' strives persistently as a 'subversive,' as a destructive, and also creative ancient force, to bring forth new forms.

In *The Civilisation of the Renaissance* Burckhardt focused on Italy of the fifthteenth and early sixteenth century, in contrast to Sismondi and Michelet, and thereby lent the term 'Renaissance' the temporal and geographical boundaries it has retained up to the present day. Burckhardt drafted the image of an epoch in the sway of violence and crime, lawlessness and tyranny, in which, however, equally the rational calculation of seizing and retaining power became established and so created the specific modern form of the 'state as artform.' The Humanists established themselves alongside the tyrants as a temporally specific human type, in whom the modern individual was embodied just as it was in the rulers. For Burkhardt they were the 'most obvious examples and victims of unbridled subjectivity' with a new intensity and sophistication of emotional life as well as a new method of rationalizing their relationship to the world. In *The Cultural History of Greece* Burckhardt describes similarly to the image of the state in *The Civilisation of the Renaissance* the Greek state, the polis, as a place of 'state slavery of the individual' in which democracy degenerated into a tyranny of the majority. Burckhardt developed the principle of agon as an essential structural feature of life in the Greek polis, the competition between individuals, yet also the bitter struggle of the poleis against one another. This principle does have destructive effects, yet at the same time it brings about the preconditions for the development of cultural freedom and a singular creative wealth. In Burckhardt's view the Greek form of religion was, however, just as constitutive as the principle of agon, as it knew neither theology, theocracy nor the rule of priests, unlike the states of the old orient, and so enabled a free development of spiritual life. As leading experts on ancient history criticized sharply, Burckhardt made a decisive contribution to the demythologization of the neohumanist–idealist reception of Greece with his portrayal of Greek society.

Burckhardt's greatest success by far among his audience, apart from *Cicerone*, was with *The Civilisation of the Renaissance in Italy*. This is due to a consciously narrative and nonscientific diction, the consistency of his analysis and references to contemporary society kept continuously alive in the subtext, which consistently refer to the dialectic of the rationalization of the individual relation to the world and the development of modern subjectivity. Burckhardt hereby made an important contribution to a structural analysis of the modern age. He overcame the thought of individuality of German historicism with his typological thinking, which orders material according to the aspect of 'cultural importance,' and anticipated Max Weber's cultural historical method. The potencies theory is reminiscent of the conception of equal systems which, however, exercise an influence over each other, or of historical areas of reality in modern sociology (Talcott Parsons for example). Burckhardt's potencies theory differs though, in that economy and society are not taken into account, and in the important position of religion and the specific function of culture, among other factors. Nor did Burckhardt, who always portrayed himself as an unsystematic thinker, develop a 'historical method.' Yet he did make an essential contribution to both the theoretical and methodological reflection of historical research. He analyzed the relationship of prejudice and historical judgement and the effects of the emancipation of knowledge from political rule and religious belief more precisely than most of his contemporaries. In the accelerated social and cultural change of the 'Revolutionary Age' he discovered an elementary compensatory need for the preservation of traditions. He encountered every tendency to political–social instrumentalization of historical knowledge, out of progressive or conservative interest, with extreme skepticism. In conscious contrast to the contemporary professionalization of historical science he retained an older, personal understanding of learning and education. Historical education should not contribute to an alteration of the outer reality, but widen the mental horizon of those seeking knowledge. With this maxim, his independent cultural historical method, and his art of portrayal he not only in fact influenced the educational horizon of those interested in history to a great degree, but also had a stimulating effect on the increasingly specialized areas of historical science (ancient history, modern history, history of art).

Bureaucracy and Bureaucratization

Abstract

Bureaucracy is an epithet, but it is also rationalization of administration. In contrast to pre-bureaucratic forms of organization, bureaucracy rationalizes reporting relationships, procedures, careers, and compensation. Even so, bureaucracy is fraught with dysfunctions, among them resistance to change, endemic power struggles, and the tendency to elaborate structure and process. Today, large firms and government agencies retain many of the elements of bureaucracy, anti-bureaucratic rhetoric notwithstanding. Conventional indexes show that the level of bureaucratization in Western societies to have remained essentially flat over the last decade. However, there has been a proliferation of new organizational forms, for example entrepreneurial organizations, network organizations, and virtual organizations, which attempt to achieve the benefits of rationalization without incurring the costs associated with bureaucratic administration.

Bureaucracy has several meanings, some positive, most negative. The sociologist Max Weber (1946) coined the term 'bureaucracy' and treated it as synonymous with rational organization: bureaucracy embodies the ideals of rational–legal authority, under which all decisions, except executive decisions, are based on rules that are internally consistent and stable over time. Political scientists tend to think of bureaucracy as governance by bureaus having the following characteristics: bureaus are large, are staffed by full-time employees who have careers within the organization, and rely on budget allocations rather than revenues from sales since their outputs cannot be priced in voluntary *quid pro quo* transactions in the market (Downs, 1967; Wilson, 1989). There is a third definition of bureaucracy, which is far less flattering: bureaucracy is inefficient organization, is inherently antidemocratic, cannot adapt to change, and, worse, exacerbates its own errors (Crozier, 1964). Discussions of bureaucracy tend to be ideologically tinged. The political left emphasizes the rationality and neutrality of government while downplaying the power of bureaucracy itself, while the right uses bureaucracy as an epithet or shibboleth and focuses on bureaucracy's antidemocratic tendencies and inefficiencies. Outside of academic circles, the rightist view of bureaucracy as inefficient and antidemocratic administration prevails. At least in the USA, very few positive references to bureaucracy can be found in the press. For most people, bureaucracy is unbusinesslike administration, an epithet or an accusation (Adler, 2012).

Bureaucracy versus Traditional Organizations

Weber's analysis of bureaucracy begins by comparing the structure of bureaucracies with traditional organizations. This comparison is made along four dimensions: differentiation, integration, constraints, and incentives.

Compared to traditional organizations, bureaucracies are highly differentiated. There is horizontal division of labor: jobs are specialized and responsibilities are strictly delimited. There is vertical division of labor as well: there are higher and lower offices, the latter subordinate to the former, all of which are ultimately accountable to the head of the organization. Perhaps most importantly, there is a clear differentiation of official duties from personal interests and obligations, what Weber calls separation of home from office. Traditional organizations, by contrast, are undifferentiated. They do not delimit responsibilities, do not separate higher from lower offices, and do not distinguish personal from official capacities-instead, the organization mirrors the stratification system of the larger community.

Compared to traditional organizations, bureaucracies have numerous integrating mechanisms, among them written rules and regulations, procedures for selection and advancement of officials, and a specialized administrative staff charged with maintaining these rules and procedures. Written rules, formal procedures, and specialized administrative staffs are largely absent from traditional organizations – actions taken by traditional organizations need not be consistent.

Compared to traditional organizations, bureaucracies constrain the conduct of officials while offering powerful incentives for compliance. There are several types of constraints: actions must be justified in terms of the larger purposes of the organization; actions must be guided by the norm of impersonality, that is, detachment and objectivity is required in all decisions; and advancement is contingent on contributing to the purposes of the organization. Traditional organizations have no distinctive purposes apart from the purposes of the people participating in them; norms of impersonality and objectivity are practically nonexistent because the organization and the community are indistinct; and there is no possibility of advancement within the organization because, again, stratification within the organization is determined by the stratification of the community.

The incentives offered by bureaucracies include the prospect of a lifetime career, salaries paid in cash rather than in kind, and (in Europe if not the USA) a modicum of prestige attached to the status of the official. Careers, salaries, and prestige based on position within the organization do not exist under traditional administration. The elements of differentiation, integration, constraints, and incentives render bureaucracies more powerful than traditional organizations yet more responsive to central

authority. The power of bureaucracies results from their capacity for coordinated action. Traditional organizations are incapable of coordinating large-scale action, except temporarily when the interests of elites coincide. The responsiveness of bureaucracies to central authority arises from top-down control of ultimate decision premises, the policies and objectives of the organization, which is impossible in traditional organizations where authority is fragmented. Paradoxically, the same elements that make bureaucracies powerful yet responsive to central authority render individual bureaucrats nearly powerless. Limited responsibilities, subordination to higher authority, and numerous rules and regulations, as well as the norm of impersonality deprive bureaucrats of latitude in decision-making. The powerlessness of individual bureaucrats, moreover, is exacerbated by their dependence on the organization for their income and social standing. Weber claims that the capacity for coordinated action, responsiveness to central authority, and dependence of individual bureaucrats on the organization promote administrative efficiency. 'Precision, speed, unambiguity, knowledge of the files, continuity, discretion, unity, strict subordination, reduction of friction and of material and personal costs – these are raised to the optimum point in the strictly bureaucratic administration...' (Weber, 1946: p. 214). The context in which Weber was writing is critical. Weber was not comparing modern businesses with bureaucracies. Rather, he was comparing bureaucracies capable of coordinated large-scale action with traditional organizations that were not.

Bureaucracy versus Business Administration

Many of the elements of bureaucracy identified by Weber are present in modern business organizations, but some are not. Like bureaucracies, large businesses are highly differentiated – jobs are specialized, a chain of command runs from higher to lower offices, and people are expected to ignore personal interest when acting in their official capacities. As in bureaucracies, many of the integrative mechanisms used are also present in large businesses, among them written regulations, procedures governing selection and advancement (today called human resource management), and specialized administrative staff. And similar constraints operate in bureaucracies and businesses – actions must be justified by the purposes (today called strategy) of the organization, norms of impersonality prevail, and advancement depends on contributing to the organization's purposes. The similarity of the administrative structures of bureaucracies and business firms occurs for several reasons. Many administrative practices arise from bounded rationality limits, people's limited capacity to make and execute complicated decisions. No .one person is capable of assembling an airplane or winning a war (Scott and Davis, 2007). Instead, complicated activities are coordinated through administrative hierarchies that transform broad decision premises (maximize shareholder value, win the war) into specific programs of action (marketing plans, battle plans) and guided by general rules that people accept as conditions of employment (Simon, 1976).

Research on organizational structures also shows that organizational size is the principal determinant of administrative structure for both bureaucracies and businesses (Blau and Schoenherr, 1971). Both bureaucracies and businesses, moreover, are constrained by norms of rationality, which means that people expect to find a chain of command, consistent rules and purposes, and rewards based on qualifications and accomplishments whether or not they are technically necessary (Meyer and Rowan, 1977).

In other respects, however, businesses and bureaucracies have evolved differently in the last 50 years. Public and private administration were similar at the time Weber was writing in the early 1900s. Much of the US public sector was modeled explicitly after the private sector at that time. It is not accidental that the reform movement in the USA, which called for governmental administration devoid of politics (or, to use another term, 'businesslike' administration), coincided with the emergence of scientific management, which called for rational selection, training, and supervision within firms. Nor is it accidental that in the 1940s, the same theory of administration was believed to apply to public- and private-sector enterprises (Gulick and Urwick, 1937). Public and private organizations have diverged in the last 50 years, however. Divergences have occurred in several domains, most notably in organizational design, accounting practices, and incentives and performance measurement. With respect to organizational design, firms now choose from among diverse organizational designs. Many larger firms have alternated between functional and divisional organizational designs, that is, between designs where the principal units are specialized by function (such as purchasing, manufacturing, and sales) so as to maximize scale economies, and designs where the principal units are self-contained businesses containing a full array of functions so as to focus attention on bottom-line objectives. Some firms have experimented with matrix organization, where people report to both product and functional managers, and still other firms have more complicated designs where some functions are centralized while others are dispersed across geographic or product units. Public bureaucracies, in contrast to business firms, exhibit very little variety in organizational design. Almost all remain organized by function as they were 90 years ago. To be sure, some central government functions have been decentralized to local governments (this is called 'loadshedding' in the USA), contracted to the private sector, or privatized outright, but the core organizational design for public bureaucracies remains functional.

With respect to accounting, public-sector agencies have departed substantially from business practice. At the beginning of the twentieth century, public entities issued consolidated financial reports and maintained capital accounts just like private businesses. Consolidated accounting gave way to much more complicated fund accounting during the 1920s, when it was believed necessary to segregate revenues and expenditures intended for different purposes into separate funds. Capital accounting has all but disappeared from the public sector – few governments distinguish between current and capital expenditures – though accounting for long-term indebtedness is retained because it is required by creditors.

With respect to incentives and performance measurement, public sector bureaucracies face more complicated issues than private businesses and, as a consequence, appear to lag substantially behind business. Businesses use several

approaches to measure and reward performance. To begin with, most publicly-held businesses define performance as total return to shareholders and reward performance so defined using techniques like value-based management. Under value-based management, executive compensation is based largely on gains in share prices, and the compensation of middle managers is based on a metric (for example, return on invested capital or economic value added) believed to drive shareholder value. The non-financial drivers of financial performance are captured in measures of internal process and customer satisfaction. Moreover, firms' internal operations are gauged against industry benchmarks assembled by third parties, usually consultants or trade associations. There is no analog to total shareholder returns in the public sector, at least none that can be easily measured – the electoral process is a coarser measure of performance than the stock market, and it is difficult to reward civil servants for electoral performance. Public agencies are taking some initial steps toward measuring non-financial performance by setting objectives and gauging progress toward them – performance measurement of this sort is part of the initiative, in the USA, to 'reinvent government' (Osborne and Gaebler, 1992) and also by measuring customer (constituent) satisfaction. Even so, competitive performance assessment hardly exists for government – the concept of benchmarking has not yet penetrated the public sector. In the USA, at least, performance comparisons across governmental units are strongly resisted, mainly on the grounds that the functions and outputs of governmental units cannot be compared across jurisdictions.

Liabilities of Bureaucracy

There is widespread agreement that bureaucracies suffer some liabilities in comparison with business. Many of these liabilities of bureaucracy are systemic in that they arise from the structure of bureaucracy rather than from people's predilections. Sociologists and political scientists have focused on what they call dysfunctions of bureaucracy, among them displacement of goals, so-called vicious circles in which dysfunctions feed on one another, and spiraling bureaucratic growth. Economists, by contrast, have drawn attention to the efficiency disadvantages of bureaucracies as compared to firms, asking whether, in general, nonmarket transactions are inefficient compared to market transactions, and, specifically, whether the funding of bureaucracies through budgets rather than market transactions results in overproduction of bureaucratic services. These potential liabilities of bureaucracy should be reviewed *seriatim*.

Displacement of Goals

Bureaucracies are known for rigid adherence to rules and procedures, even when rules and procedures appear to impede the objectives of the organization. The notion of goal displacement provides both a description and an explanation for this seemingly nonrational conduct. Goal displacement, following Robert K. Merton (1958), describes the process whereby means become ends in themselves, or 'an instrumental value becomes a terminal value'. The displacement of goals is especially acute in settings – such as bureaucracies – where the following conditions exist: the technical competence of officials consists of knowledge of the rules; advancement is contingent on adherence to the rules; and peer pressure reinforces the norm of impersonality, which requires rules and procedures to be applied with equal force in all cases. What is important is that goal displacement, at least as originally conceived, argues that bureaucracies are efficient in general – under conditions anticipated by their rules and procedures – but inefficient in circumstances that cannot be anticipated. The implications of goal displacement for innovation and new product development have been realized only gradually: bureaucracy can be antithetical to innovation.

Vicious Circles

A more thorough critique of bureaucracy argues that dysfunctions are normal rather than exceptional and, moreover, that dysfunctions accumulate over time such that organizational stasis is the expected outcome. The elements of the vicious circle of bureaucratic dysfunctions are impersonal rules that seek to limit the discretion of individual workers, centralization of remaining decisions, isolation of workers from their immediate supervisors as a consequence of limited decision-making authority, and the exercise of unofficial power in arenas where uncertainty remains.

Thus, as Michel Crozier observes (1964), maintenance people exercise undue influence in state-owned factories because their work is inherently unpredictable and cannot be governed by rules. The logic of vicious circles, it should be pointed out, yields several consequences. To begin, new rules will arise to eliminate whatever islands of power remain in the organization, but these rules will trigger further centralization, isolation, and power plays as new sources of uncertainty arise. Additionally, to the extent that the organization is opened to uncertainties arising externally, line managers have the opportunity to reassert power that would otherwise erode through the dynamics of vicious circles. External crisis, in other words, may be an antidote to bureaucracies' tendency toward rigidity over time.

Spiraling Growth

Bureaucratic systems also tend toward growth, other things being equal (Meyer, 1985). Until recently, growth of government and of administrative staff in private firms was endemic. The causes of growth lie in several factors, but chief among them are people's motives for constructing organizations in the first place. People construct formal organizations in order to rationalize or make sense of otherwise uncertain environments; organizations, in fact, succeed at making the world more sensible; as a consequence, there is continuous construction of bureaucracy and hence bureaucratic growth as people attempt to perfect their rationalization of an inherently uncertain world. Three comments are in order.

1. The logic of bureaucratic growth is built into neoclassical administrative theory developed by Simon (1976) and others. Irreducible uncertainty in the environment, in conjunction with the belief that administrative organization can rationalize uncertainty, will result in continuous growth in administration.

2. The growth imperative is so strong that deliberate campaigns to 'downsize' or 'restructure' organizations must be launched in order to achieve meaningful reductions in staff.
3. Inefficiency. Economists have asked persistently without resolution whether bureaucracies are inherently less efficient than private-sector enterprises. Several answers have been proffered, none fully satisfactory.

From the 1940s to the present time, the Austrian school of economics, von Mises (1944) and others, have argued that any departure from market principles yields both inefficient transactions and antidemocratic tendencies. This position has proved difficult to reconcile with contemporary transaction-cost theories (Williamson, 1975), which argue that hierarchies may be more efficient than markets under some circumstances. In the 1970s, the efficiency question was cast somewhat differently: might bureaus, which depend on budgets for their sustenance, overproduce compared to firms subject to the discipline of the market? (Niskanen, 1971) Here too the answer was equivocal, as analysis showed that rent-maximizing monopolists would have similar incentives to overproduce whether they were located in public bureaucracies or private firms. Despite the uncertain analytic underpinnings for the belief that bureaucracies are more apt to harbor inefficiencies than private-sector organizations, privatization of governmental functions is occurring rapidly and with positive results in many countries. It is unclear whether the liabilities of public bureaucracies are simply the liabilities of established organizations that have been shielded from extinction for too long, or whether bureaucracies suffer disadvantages in comparison with private organizations because of weak incentives and inconsistent objectives.

Research on Bureaucracy

Organizational research and research on bureaucracy were once synonymous or nearly so, as the bureaucratic model was believed descriptive of all organizations, for-profit, non-profit, and governmental. Case studies of bureaucracy written during the 1950s and 1960s encompassed government agencies and industrial firms alike as evidenced by titles like Gouldner's (1954) *Patterns of Industrial Bureaucracy*. Early quantitative research on organizations, such as the work originating at Aston University and the University of Chicago, focused mainly on relations among elements of organizational structure (size, hierarchy, administrative ratio, formalization, centralization, etc.) that flowed from the bureaucratic model implicitly if not explicitly. As attention shifted to external causes of organizational outcomes, however, the bureaucratic model has become less relevant to organizational theory. Thus, for example, the key causal variable in resource dependence models of organizations (Salancik and Pfeffer, 1978) is control of strategic resources, which is more germane to businesses than to government bureaus. The key dependent variables in organizational population ecology (Hannan and Freeman, 1984) are births and deaths of organizations, which are infrequent in the public sector (see Kaufman, 1976). The new institutional theory of organizations has downplayed Weber's notion of bureaucracy as rational administration and has substituted for it the notion that all organizations, bureaucratic and nonbureau- cratic alike but especially the former, pursue social approval or legitimation by appearing to be rational rather than actual efficiency outcomes. Almost alone among major organizational theorists, Philip Selznick argues that the problem of bureaucracy remains a central issue in organizational theory: '... the ideal of an effective, fair, and responsive bureaucracy remains elusive. Our society desperately needs organized ways of dealing with social problems; we cannot rely solely on market strategies. Yet the specter of bureaucracy still haunts and repels, still saps public confidence and weakens support for collective action' (Selznick, 1996: p. 276).

Several streams of research on bureaucracy remain, although they are at the periphery of organizational theory. One stream of research, largely in the field of public administration, focuses on the possibility of bureaucratic reform, of reducing the otherwise endemic dysfunctions of bureaucracy. This research does not promise solutions; quite the opposite, it finds bureaucratic dysfunctions intractable. For example, reform initiatives almost inevitably create new positions for people to oversee the reform, resulting in new layers of administration and 'thickening' of each layer (Light, 1997). Decentralizing managerial authority in public bureaucracies is offset by a corresponding centralization of political authority, with little net improvement in efficiency or responsiveness (Maor, 1999). Attempts to 'reinvent government' by reshaping bureaucracies into so-called performance-based organizations are usually frustrated by conflict over what the performance standards should be (Roberts, 1997).

Another stream of research, pursued mainly by economists, focuses on the impact of incentives and performance standards on performance outcomes in bureaucracies. The tentative conclusions of this research are, again unpromising (Carnis, 2011). Only weak incentives are available in bureaucracies. Not only do bureaucracies perform multiple tasks, but they also answerable to multiple constituencies or, in the argot of agency theory, principals. Multiple tasks weaken incentives in all organizations because the outcomes of some tasks can be more readily observed than the outcomes of others. Multiple constituencies or principals, however, are unique to bureaucracies and further weaken incentives because each constituency will bargain separately with the bureaucracy (Dixit, 1996). Specific performance standards built into legislation do discipline the behavior of bureaucrats somewhat, but measures of short-term results can work against long-term objectives and are frequently gamed (Heckman et al., 1997).

Abstract

Bureaucracy is an organizational form that became dominant in business, government, and other arenas during the nineteenth and twentieth centuries. Since then, extensive debates among sociologists and others have centered on its nature, rationality, and social impact. This article reviews the major arguments, beginning with Max Weber's foundational ideal type and addressing subsequent work on bureaucracy's informal and cultural dimensions, external influences, internal contradictions, and pitfalls of societal bureaucratization. While some have proclaimed bureaucracy's demise amidst today's postindustrial economy, evidence suggests that it lives on – with consequences that are just as ambivalent as in Weber's time.

Bureaucracy can be understood as a form of organization that features elaborate rules and regulations, a division of labor, and a hierarchical command structure, all rationally designed to achieve established goals. Though such organizations have existed since ancient times, the term – based on *bureau*, French for 'desk' or 'office' – emerged in eighteenth century Europe, where bureaucracy proliferated alongside the expansion of large-scale commercial enterprise and centralized government agencies. The first English usages, in the 1800s, referred to bureaucracy as a 'complication of intrigues', a 'tyranny', and an 'evil', suggesting that the concept has never been without mixed evaluations and meanings (OED online, 2013; Williams, 1983 [1976]). This extends to the sociological literature on the topic, where relatively neutral analysis is accompanied by extensive critical discussion of the consequences (mostly negative) of bureaucratic organizations and the bureaucratization of modern society. Although some critiques target a straw man, most have been productive, enabling sociologists and others to better understand not only bureaucracy but also alternate forms and organizations in general. To see this, it makes sense to begin with sociology's early and appreciative treatments of bureaucracy and then examine the critical assessments that followed.

The Weberian Ideal Type

Most contemporary sociological discussion of bureaucracy refers explicitly or implicitly to the ideal type formulated by Max Weber in the early 1910s and first published in English translation in 1946. This conceptual model was based mostly on observations about government and commercial administration, but Weber and others have also used it to describe religious, educational, military, and other organizations. By this definition, the key feature of any bureaucracy is its basis in rational-legal authority, a form of domination that is accepted as legitimate by subordinates because it rests on legally enacted formal rules and on the commands of leaders chosen in accordance with them. In addition to providing legitimacy, rules – such as laws, administrative regulations, policies, or standard operating procedures – are rationally designed to facilitate achievement of the organization's goals. Thus, they permeate and define bureaucracy. Staff follow rules more than rulers: their work centers on carrying out officially prescribed duties rather than obeying superiors' personal commands, especially should the latter diverge from the former. Even the highest leaders are bound by rules; the 'chief' does not use his or her position to achieve private ends, but instead acts as the organization's 'first official' or even 'first servant' (Weber, 1978 [1921]: p. 957). The affairs of those subject to bureaucratic authority (e.g., citizens, customers, clients, etc.) are handled by the rules, not in accordance with their personal needs, connections, or identities. Rules structure bureaucratic organizations by specifying the duties and limits of particular jurisdictions within their typically elaborate divisions of labor, and by establishing hierarchies of authority and procedures for appealing commands from below. The importance of rules can also be linked to other defining features of bureaucracy, such as the separation of personal from official action and property, the appointment of staff based on technical expertise and formal qualifications, and the proliferation of records and files.

Weber saw the proliferation of bureaucratic organizations as part of a modern, Western trend toward rationalization, or increased use of means-ends reasoning in all areas of life. As with other aspects of this shift he was profoundly ambivalent about it. His assessment of the benefits and drawbacks of bureaucracy is probably best appreciated by understanding the contrast he draws between it and other organizational forms that prevailed in premodern times. Among the most common were patriarchal and patrimonial organizations, both based on traditional authority, or belief in the sacredness of age-old traditions and in the legitimacy of those ruling in accordance with them. While bureaucracy involves adherence to abstract rules, these organizations rest on personal loyalty to a traditionally chosen leader and obedience to his commands. It is the leader, not fixed rules, that determines the organization's goals, structures, and actions. The leader also chooses staff, typically based on personal relationships rather than formal qualifications. Further, official resources can legitimately be used for personal gain, which is not necessarily viewed as distinct from organizational goals so long as its pursuit does not violate tradition. Less common but also important historically were organizations based on charismatic authority, or devotion and

obedience to an individual leader due to his (or rarely, her) exceptional characteristics, such as genius or prophecy. Charismatic organizations tend to have fairly simple structures, with staff appointments based on personal connection or resemblance to the leader.

Given these reference points it may be easy to see why Weber thought bureaucracy to be technically superior to other organizational forms. Bureaucratic organizations are able to accomplish their goals with optimal "precision, speed, unambiguity … [and] reduction of friction and of material and personal costs" (Weber, 1978[1921]: p. 973) because there are staffed by individuals selected for their qualifications rather than their personal connections, and because officials treat their work as a vocation rather than an opportunity for personal benefit. Further, bureaucratic organizations can operate predictably, continuously, and indefinitely because they are built on rationally designed rules, while traditionalist and charismatic organizations are guided by the variable whims, abilities, and interests of their individual rulers. For these reasons, Weber thought bureaucratic organization to be almost necessary for commercial enterprise and government in modern, capitalist democracies. The impersonality of bureaucracy – its ability to operate without regard for specific persons or their ascribed statuses and privileges – makes it a fitting vehicle for "all pursuits of naked economic interests" (Weber, 1978[1921]: p. 975) and also for the exercise of mass democracy, which rejects privilege and demands formal equality.

However, Weber recognized that these very strengths of bureaucracy could also have negative consequences. First, what makes bureaucracy predictable and precise is that its power is vested in its rules and structure, rather than in people. This means that it disempowers its own staff: "the individual bureaucrat cannot squirm out of the apparatus into which he has been harnessed" (Weber, 1978[1921]: pp. 987–988). Also, the fixed rules, hierarchies, and divisions of labor that enable bureaucracies to operate continuously tend to become entrenched, making them difficult to alter or destroy. Further, a great irony of bureaucracy is that its emphasis on precise adherence to rules may lead to a situation in which formal rationality – Weber's term for technical, procedural calculation – gets in the way of substantive rationality, or reason directed at achieving the organization's ultimate values and goals. The relationship between bureaucracy and democracy is also fraught with contradictions. Because appointments are made based on formal qualifications, bureaucracy does entail a democratic leveling of ascribed inequalities such as feudal privileges. However, it also creates a new governing class of trained, qualified experts and thus, in its pure form at least, is not fully compatible with popular rule. Together, bureaucracy's impersonality, emphasis on formal rationality, and disempowerment of both staff and subjects combine to give it a "cool 'matter-of-factness'" that eliminates "love, hatred, and all purely personal, irrational, and emotional elements with escape calculation" (Weber, 1978[1921]: pp. 980, 975). The more bureaucracy becomes a technically perfect administrative machine, the more it becomes meaningless, and thus its growth helped transform modern society into what Weber described as a rationalized and disenchanted 'iron cage'.

Critical Approaches

Aside from this last commentary, Weber attempted to remain neutral in defining bureaucracy and weighing its consequences. Although his ideas were widely accepted, many subsequent authors have taken a more explicitly negative stance. Some critiques center on the shortcomings of Weber's ideal type, while many target bureaucracy itself, challenging its rationality by pointing to general flaws or specific conditions in which it becomes inefficient. Finally, a number of authors have addressed the negative effects of growing bureaucratization on the societies in which it occurs. We will review these themes in turn.

Departures from Weber's Model

Critics of Weber's ideal type usually do not claim that it is mistaken about the essential characteristics of bureaucracy (e.g., rules, hierarchy, division of labor, etc.), but rather that it fails to include features that are empirically evident in real bureaucratic organizations. In particular, following a common typology originated by Gouldner, Weber's definition can be understood as a 'rational systems' model which emphasizes the conscious, calculated manipulation of organizational rules and structures to achieve established goals. Partisans of the competing 'natural systems' approach see organizations as spontaneously developed, organic entities that evade such deliberate control. They fault Weber – and/or his rationalist successors in organization studies – for overemphasizing formal structure and neglecting informal relations and culture.

Recognition of the importance of informal organizational life – the unofficial relationships, groups, norms, and prestige rankings that emerge spontaneously through day-to-day workplace interactions – came early and has been a persistent feature of ethnographic research on bureaucracies. Melville Dalton's (1959) *Men Who Manage* showed that the everyday operation of bureaucratic firms was governed more by informal cliques, rivalries, and favor-swapping than by formal command hierarchies, and that some managers had informal influence that rivaled the power of their formal superiors. These findings were echoed in Robert Jackal's (1988) subsequent study of corporate managers, *Moral Mazes*, which claimed that formal bureaucracy may prevail at lower managerial ranks, but at the highest levels it is blended with a patrimonialism that features fealty relations to superiors, promotion based on connections rather than achievement, and clique-based power struggles. Both works suggest that the informal side of bureaucracy is just as important as formal structure in explaining organizational action. Gouldner's earlier (1954) *Patterns of Industrial Bureaucracy* went further claiming that whether and how official bureaucratic rules are enforced is in fact decided through informal negotiations between workers and managers. Here, informal relations actually determine formal structure rather than simply coexisting with it.

Culture – the meanings, beliefs, values, norms, and symbols that are shared within organizations – has also been emphasized in recent research, where it is alternately seen as a cause or an effect of structure. Some scholarship focuses on how organizational cultures originate and vary at the societal level (Crozier, 2009[1964]; Dore, 1983), while others see

intranational diversity in organizational cultures as a deliberate result of managerial choices or an unintended effect of structural variation (Morrill, 1995); still others emphasize the distinctive subcultures that emerge within particular organizational subunits via day-to-day interaction (Jackall, 1988; Morrill, 1995). Regardless of origin, organizational culture is thought to have important consequences. Many have emphasized its positive functions, such as bringing members together and giving them a shared sense of purpose, though less sanguine outcomes are also possible (Smircich, 1983). One effect that has received extensive attention is 'normative control', in which organizational members' actions are directed by cultural norms and values that encourage their spontaneous assent to and compliance with organizational objectives. How this relates to bureaucratic control is a matter of some dispute. Ouchi (1980) sees them as alternatives, arguing that normatively controlled 'clan' organizations emerge only when bureaucratic structures fail, typically due to ambiguity in evaluating individual contributions and consequent inability to elicit cooperation among members. An important counterpoint is provided by Kunda's (1992) ethnography of a high technology company where control was achieved less through typically bureaucratic formal mechanisms than with strong norms and values that made employees 'want to' achieve corporate goals. Though this might seem to exemplify culture replacing bureaucracy, Kunda instead argues that culture had itself become bureaucratized: "The essence of bureaucratic control – the formalization, codification, and enforcement of rules and regulations – does not change in principle under a system of normative control; it merely shifts its focus … from the organizational structure to the organizational culture, from the members' behavior to their experience" (p. 220). Thus, strong culture and bureaucracy may be complements rather than substitutes.

Bureaucratic Contradictions

While natural systems theorists fault the Weberian bureaucratic model for overemphasizing formal structure, they typically do not contest the claim that this structure is, in itself, rational and efficient. Other scholars do, and here two streams of thinking are particularly important. One suggests that the (in)effectiveness of bureaucratic structures depends on their external environments, while the other focuses on structural irrationalities intrinsic to all bureaucracy.

Though he acknowledged social context, Weber's focus was largely intraorganizational. This emphasis became even stronger in successive scholarship, and thus it was not until the popularization of 'open systems' approaches in the 1960s that scholars began in earnest to examine how organizations are affected by their environments (Scott, 2004). Importantly, the resulting theories do not focus exclusively on bureaucracy; instead, they view the adoption of any organizational form, bureaucratic or otherwise, as influenced by contextual conditions such as levels or types of change, trust, information, power, competition, and legitimacy. One of the earliest open systems models was contingency theory, which suggests that the efficiency and success of any organizational type depends on its ability to successfully address environmental characteristics such as rate of technological change and degree of certainty about competitive conditions; bureaucratic forms are thought to be best suited to stable and certain environments (Burns and Stalker, 1961; Lawrence and Lorsch, 1967). The economic theory of transaction costs uses a similar logic of necessity to draw different conclusions: bureaucracy is not a response to but a way of creating environmental stability. When economic coordination can no longer be achieved through market exchange due to problems of bounded rationality and possible malfeasance, bureaucratic organizations emerge to reduce uncertainty and limit opportunism (Williamson, 1981). This occurred in America and elsewhere following the technological revolutions of the late nineteenth and early twentieth centuries, as increasingly complex and long-distance commercial transactions came to require the careful coordination of bureaucratic managers (Chandler, 1984). Resource dependence theory also focuses on coordination across organizational boundaries, but rather than costs it emphasizes the power asymmetries that can arise when, for instance, one organization depends on another for vital inputs that it cannot obtain elsewhere. Though such imbalances need not lead to bureaucracy they do suggest that organizational decisions, including those regarding structure, may be profoundly shaped by pressures from external parties (Pfeffer and Salancik, 2003[1978]). Similar conclusions are drawn by network theorists who examine how organizational characteristics, including bureaucratic structure, are affected by positioning in networks of competitors, suppliers, customers, workers, or other entities (Granovetter, 1985). A more cultural approach is found in the new institutionalist school's explanation of bureaucratization as the result of isomorphism, a process in which external institutional influences – demands from government and other powerful actors, uncertainty-driven imitation of other organizations, pressures from professional organizations – cause organizations to adopt similar bureaucratic structures due to high legitimacy (in the modern industrial West, at least) rather than because they yield efficiency gains (DiMaggio and Powell, 1991[1983]). Finally, organizational ecologists focus on how macrolevel trends in organizational structure, including bureaucratization, result from organizational births and deaths, which are in turn shaped by environmental conditions of legitimacy and competition (Hannan and Freeman, 1989). New organizational forms initially have few births and many deaths because they lack legitimacy; if they manage to proliferate and gain it, their spread will then be limited as increased competition for scarce resources leads to fewer births and more deaths. Overall, open systems accounts vary considerably but share the claim that no organizational form is likely to prevail under all conditions. Bureaucracy grows when mass production and distribution creates complex coordination needs, when industrial stability is high, and/or when rational-legal legitimacy dominates the cultural landscape; under different circumstances, other organizational forms become more efficient, acceptable, and common.

However, another line of critique claims that even under the best circumstances, all bureaucracies suffer from internal flaws that contradict any claims to optimal efficiency. First, while Weber emphasized impersonality, later authors have characterized bureaucratic rationalization as downright dehumanizing – particularly when extended onto the factory floor through 'scientific management' of the labor process (Braverman, 1974). The human costs of this movement toward rigid,

mindless tasks and worker disempowerment became evident in the strikes it provoked; the organizational limitations were illustrated by the famous Hawthorne experiments, which showed that factory workers who were granted some discretion, interaction opportunities, and a sense of organizational importance outproduced those in more strictly rationalized settings. These findings became foundational for the human relations school of management, which focused on increasing productivity by treating workers as fully human, emotional, and social beings, and criticized bureaucratic tendencies to turn the workplace into an alienating machine (Kanter, 1977). Further, bureaucracy may endow its inhabitants with 'trained incapacity', Veblen's (1914) term for the inability of highly specialized workers to function beyond their narrow task areas. This results from extensive division of labor, which many have seen as central to bureaucratic rationality; in contrast, Veblen noted that staff members' blindness to business needs outside their immediate purviews could lead to "discrepancies, obstructive tactics, and disserviceable practices" (p. 248). Just as threatening to bureaucratic efficiency, especially at the highest levels, is the "Peter Principle" which suggests that "in a hierarchy every employee tends to rise to his level of incompetence" (Peter and Hull, 1969).

In addition to negative effects on employees, bureaucracy also involves more systemic problems. Echoing popular complaints about 'red tape', scholars ranging from early contingency theorists to recent students of postindustrialism have assailed the rigidity of the bureaucratic form, which prevents it from successfully innovating or adapting to a changing environment (Burns and Stalker, 1961; Saxenian, 1994). Perhaps most damning, bureaucracies may carry out actions quite distant from those they were designed to achieve. Merton (1949) used the term 'goal displacement' to describe how emphasis on formal procedure can turn rules and regulations into the ends rather than means of bureaucratic action; in such cases, "primary concern with conformity to the rules interferes with the achievement of the purposes of the organization" (p. 254). Crozier (2009[1964]) claimed that formal regulations and centralization of control result in 'vicious circles' which prevent bureaucracies from learning from their mistakes and thus interfere with the accomplishment of organizational goals. With these observations, we come full circle from Weber's claims about bureaucracy's technical superiority to arguments that it has quite irrational outcomes.

Finally, many critics are less concerned with bureaucracy's internal (ir)rationalities than with the consequences of widespread bureaucratization for the societies in which it occurs. First, the tension between bureaucracy and democracy was identified by Weber but examined with far greater pessimism by his contemporary Robert Michels. Based on a study of political parties and labor groups, Michels (1915) claimed that all democratic movements require organizations, but that as such organizations grow they develop bureaucratic structures with specialized leadership cadres who limit participation from below and use organizational power to benefit themselves rather than the masses they ostensibly serve. According to this 'iron law of oligarchy', bureaucracy is the inevitable but inevitably antidemocratic outcome of democratizing trends. In addition, the relationship of bureaucracy to ascriptive inequalities has received much attention. To some, bureaucracy vastly improves on the sexism and racism of patrimonial organization because its formal hiring procedures limit managers' ability to use ascriptive biases in selecting candidates (Reskin and McBrier, 2000) and because it actively promotes logics of universalism and meritocracy (Baron et al., 2007). However, others argue that bureaucracy furthers ascriptive inequality. For instance, extensive divisions of labor permit bureaucratic organizations to marginalize minorities and women in areas that are low-status, low-paying, and often racialized or gendered, e.g., affirmative action or ethnic marketing positions, thereby perpetuating employment inequality (Collins, 1989). Kanter (1977) takes this further, noting that bureaucratic hierarchies elicit different behaviors from staff with different levels of power and opportunity. Women and minorities have long been clustered in low-power positions and often exhibit associated behaviors such as rules-mindedness and territoriality, but through stereotyping these are attributed to their ascribed identities rather than their positions. As such behaviors are not deemed suitable for leadership positions, the stereotypes hinder these groups' upward movement within organizations. Acker (1990) makes an even more damning argument, claiming that bureaucratic organizations are inherently gender-biased because their constitutive structures, symbols, and behavioral expectations are built on the androcentric logics of surrounding societies. For instance, the bureaucratic concept of an ideal worker rests on an ostensibly genderless but actually masculine image of an individual "whose life centers on his full-time, life-long job, while his wife or another woman takes care of his personal needs and his children"; women, who cannot achieve such qualities because "to do so is to become like a man", are marginalized (pp. 149–150).

Lastly, bureaucratization has been famously assailed for its impact on the character and the temperament of the societies in which it has occurred. This began at least with Weber, for whom bureaucratization and other forms of rationalization replaced purposeful, value-oriented actors with 'specialists without spirit' and 'sensualists without heart' (1930[1904]: p. 124). The critique was extended to the American context by C. Wright Mills, whose *White Collar* (1951) described a shift in national outlook from the independence and entrepreneurialism of the nineteenth century farmer or businessmen to the dependence and powerlessness of the twentieth-century bureaucrat, the unheroic 'little man' "living out in slow misery his yearning for the quick American climb" (pp. ix–xx). William H. Whyte's more famous *Organizational Man* (1956) faulted bureaucratization for the demise of American individualism and its replacement by a 'social ethic' that emphasized group conformity and discouraged adherents from taking their conscience and destiny into their own hands.

Bureaucracy Today

More recently, numerous social scientists have suggested that bureaucracy's era is over and that it is rapidly being replaced by other organizational forms. The primary culprit (or hero, to some) is increased economic turbulence since the mid-1970s,

a product of new technologies and increasingly international, specialized, and competitive markets. Drawing on the logic of contingency theory, many scholars have surmised that under such conditions, both mass production and the bureaucratic forms that typically accompany it have grave disadvantages because their large size and complex hierarchical structures make them slow to innovate and adapt to change (Piore and Sabel, 1984; Saxenian, 1994). Thus, the world described by Whyte and Mills has given way to a new economy comprised of 'postbureaucratic', 'postindustrial', 'post-Fordist', 'flexible', and/or 'networked' organizations (Heydebrand, 1989; Piore and Sabel, 1984; Powell, 2001; Wood, 1989). Regardless of nomenclature, these new forms share some characteristics of the nonbureaucratic 'organic' organizations originally identified by contingency theorists Burns and Stalker (1961): flexible and multiskilled jobs rather than rigid divisions of labor, control via collaboration in a relatively 'flat' networked structure rather through a command hierarchy, and an emphasis on worker participation and commitment. They also have features that Burns and Stalker did not anticipate, notably including heavy use of contingent labor such as temporary, freelance, and subcontracted work (Heydebrand, 1989; Powell, 2001). Whether these turns away from bureaucracy are positive, particularly for workers, is the subject of rather polarized debate, with some linking them to increases in skill and autonomy while others emphasize the potential for labor intensification, neopatrimonialism, and insecure employment (see Powell, 2001; Smith, 1997; Vallas, 1999; Wood, 1989 for reviews).

Further, an even more recent line of scholarship suggests that bureaucracy's downfall has been overestimated. Ritzer (1993) claims that small eddies of postindustrialism have done little to stem the rising tide of McDonaldization, in which logics of bureaucratization and rationalization are greatly intensified through the application of the fast-food principles – efficiency, predictability, quantification, and control – to all areas of social life, including workplaces but also health, education, recreation, and the family. Similarly, Head (2003) points out that rather than embracing flexibility and collaboration, many firms have responded to economic distress by adopting new, hi-tech productivity practices such as business process reengineering and enterprise resource planning, which extend bureaucratic regulation to new levels of exactitude and new categories of workers. Others argue that bureaucracy may have waned but is today making resurgence, albeit often in new, more flexible hybridized forms, and that contrary to popular opinion this is not necessarily for the worse (du Gay, 2005; Piore, 2011). For workers, the insecurity, particularism, and insidious normative and peer controls found in 'flexible' firms may make formal structure look enticing (Barker, 1993; Kunda, 1992). More generally, after roughly three decades of experience with the consequences of ever-less-regulated market capitalism – Enron, the Dotcom bubble, the mortgage crisis and Great Recession, spiraling economic inequality, the Bangladeshi factory collapse, ongoing environmental degradation – many see bureaucratic emphases on planning, structure, accountability, transparency, and universalism as virtues rather than vices. For better *and* for worse, bureaucracy remains a persistent feature of the contemporary world.

Bureaucratization and Bureaucracy, History of

Rolf Torstendahl, Uppsala University, Uppsala, Sweden

Abstract

Bureaucratization as a term is discussed, and its relation to the history of bureaucracies is developed. A main distinction is made between societies that have differentiated the political power from the administrative power and those that have not. Colonial rule has formed an intermediate type, as colonies were almost entirely governed by appointed administrators, while this was not possible in Europe or the United States. Bureaucratization is not just a state phenomenon, and big business in the private sector has become more and more dependent on an efficient administration. The interrelation between welfare and bureaucracies has been observed, and a current debate is going on about the relation between democracy, bureaucracy, and welfare.

Bureaucratization is a process, and the term in itself thus refers to a historical development. It is, however, used in several distinct meanings, some of which refer to moral and political values, which are endangered by a growth of bureaucracy according to a common belief. As a descriptive term, apart from its evaluative content, bureaucratization may mean (1) a growth of numbers of administrators and administrative organs between points of reference, (2) a growth in administrative complication in the handling of matters, and (3) an increase in administrative competence and independence and in the functional division of administration. These three definitions may be interrelated, although this is not necessarily the case. The third one comes close to the analysis first made by Max Weber of the development of a bureaucratic principle (Weber, 1922).

There is also a great difference in the use of the term in different contexts. Here one may distinguish first (1) a reference to state administration only or (2) a reference to any sort of administration, whether public or private.

A third distinction may also be made. Sometimes the term bureaucratization is used in regard to states and societies irrespective of their political system. On other occasions the use is restricted to states and societies where a separation is made, at least in principle, between political and administrative duties and responsibilities. The latter limited scope of the term is, of course, much more related to the near history than to past centuries, with the nineteenth century as an intermediate period when this separation first came to be more commonly observed.

The different aspects of the concept of bureaucratization and their close relationship to political ideals regarding the scope of state interference in relation to citizen's rights and the division of responsibility between politicians and bureaucrats make it difficult to use the concept in historical and social science analysis. However, in regard to changes in power and control, it covers an important reality, which has to be differentiated from the use of administration in general. The following account goes out from Weber's analysis combined with the distinction between political and administrative responsibilities.

From Antiquity to the Nineteenth Century

There is a striking difference between the state of Egypt in Antiquity, the Mesopotamian empires of Babylon and Assur, or Rome compared to the Medieval states of Europe including the vast empire of Charles the Great. This difference has to do with the ambitions of the state. While delegation to subprinces was the rule in the feudal system that emerged in medieval Europe, the state was in principle centralized as to the important decisions in the early empires. It is often said that these empires were highly bureaucratized. The Russian historian of Antiquity Michail I Rostovcev in the first half of the twentieth century wrote several books in which he tried to show that the process of bureaucratization was going on in Egypt, the Hellenistic Empires, and the Roman Empire (Rostovcev, 1936–38, 1941, 1957). In spite of his brilliance his views are not current among ancient historians of today. Some would rather stress the limits of state power in Antiquity and others the specific structure of the ancient system of government in different parts of the world. What was common to these regions was the fusion of politics with administration. No real difference was made, and only the king or emperor exerted a political power meant to express a deliberate policy. He headed an organization where the highest officials had some political duties, but their policy making had mostly to be concealed under administrative clothing. Further down in the hierarchy, the administrative chores were the real occupation of the employees. Often, administrators were neither full-timers nor independent, and regulations tended to vary with the will of the ruler. Further, it is important that the state in Antiquity was highly centralized and that no clear difference was made between public law and private law until the late Roman Empire and, thus, no real limit was set between state obligations and rights and a private sector. Mostly the kings and emperors commanded only 'their' servants and demanded only what belonged to them, although whether these relations were of private or public nature was often not quite clear. This 'bureaucratic' state was, thus, vague in its boundaries, but, as a centralized state, it needed an efficient bureaucracy. It is hardly evident that bureaucracy should have grown or extended its procedures from one period to another or from one empire to another during the period before AD 400.

China was in many ways the same sort of bureaucratic political state as imperial Rome, but the Chinese system started earlier and continued in all the dynasties up to the end of the empire in 1911. The Confucian class of state servants was hierarchically ordered under the emperor, who had the political power in his hands. No real delegation of political power

was used, but rather a blend of political and administrative obligations, which included a strict rule regimen. The bureaucracy was organized in a refined system already in the Ch'in and Han dynasties (221 BC–AD 220). There were ministries and ministers, but even these, and some senior officials or 'excellencies' who were the highest in rank, could influence policy only via their channels to the emperor. Their responsibilities did not include the task to form a policy even for the field for which they were responsible. Hierarchy was enormously developed both within each ministry or office and also in the country as a whole. Local administration took place via organs in at least five different levels. However, it will seem that all political decision making stayed with the emperor in spite of a system of checks and balances within the bureaucracy (Loewe, 1986; Bielenstein, 1986).

The politico-bureaucratic system of China, Egypt, and imperial Rome under Antiquity did not change in principle, which makes it difficult to use the term bureaucratization in each of the cases. The fundamental structure of bureaucratic government did not develop even though specific modifications were introduced in the division of tasks and responsibilities. Except in China, Korea, and Japan, a fundamental debureaucratization took place in the centuries after AD 400. In the nomad empires of which that of the Mongols was by far the most extensive, virtually no bureaucracy existed. When the Mongols had taken China, the Chinese system of government became theirs but not in the parts of the empire that broke away from Mongol China. Bureaucracy was also kept small in the Arab and Islamic states, which were rapidly formed in the seventh to tenth centuries. European feudal princes had very few officials who were employed to administer; such officials seldom had full-time employment for their administrative work, and they could almost never rely on a rule system, which might ensure a field for decision making without interference and with some autonomy. Within the Catholic church a system resembling a bureaucracy survived.

Only with the rise of central power in the fifteenth to seventeenth centuries did administrative institutions grow again in Western Europe; in Eastern Europe the same system existed for much longer, in Russia until 1905 and partly until 1917. There are many similarities between this system of bureaucratic forms of government and the one in ancient China and Rome. A specific instruction for future bureaucrats emerged. Universities played a role in this, and China had such educational institutions from an early date. In Europe two different types of reforms increased the theoretical competence of the bureaucracy. First, in centralized monarchies there was a need for educated secretaries and fiscal employees, who could master the subtleties of foreign and internal relations and international and national law. This need was partly met through recruitment of low-estate university men, who were sometimes promoted into the nobility (the 'noblesse de robe'). Second, nobles who wanted to preserve for nobles influential posts in the immediate vicinity of central power, arranged specific educational institutions for young nobles, to make them fit for bureaucratic leadership. It also became customary to send young nobles to universities in a tour over Europe to polish their education in a fitting way. Centralized monarchy in this manner again made bureaucracy important in the European way of handling public affairs. The well-functioning of the administration of the state was a precondition for efficiency in foreign policy and warfare, and these were the ultimate aims of most of these monarchies (Raeff, 1983; Yeroshkin, 1997). In the middle of the seventeenth century military entrepreneurs were finally made servants of the state and a military bureaucracy evolved. Later 'cameralism,' the 'science' of civil administration, developed mainly in the German states (Mann, 1986/1993). The relatively poor Swedish state became a power of significance partly because of the efficiency of its bureaucratic apparatus, organized in 'collegia' defined according to functional criteria, and with (in principle) salaried employees. This organization impressed Peter I of Russia, so that he reformed the Russian bureaucracy according to the same model, although it was soon modified by his successors (Peterson, 1979; Shepelyov, 1999).

The new European bureaucracies represented some innovations in the process of bureaucratization of state and society. Some of the state bureaucrats of the seventeenth and eighteenth centuries had a real full-time employment and were salaried for their services, and rules were established to ensure that the administrations worked in an efficient manner and on a daily basis.

In the seventeenth- and eighteenth-century rush to make non-European regions dependent in the form of colonies, European states transferred part of their bureaucratic system to their colonies. When the agent was not a state but a company, like the British East India Company (EIC), it in fact acted as a quasi state and formed its own 'public' bureaucracy (Stern, 2011). This exceptional form of bureaucratization, affecting both the EIC and vast regions in India, had no counterpart in Europe.

Bureaucratization and Parliamentary Politics from the Early Nineteenth to the Early Twenty-First Century

The development of bureaucratization took a new turn from the nineteenth century in Europe and the United States, and because of European imperialism and the domination of these countries in world politics and economy this new turn made a global impact. The first half of the century was filled with parliamentary and bureaucratic reforms, and the second half saw different stages of democratization take place. Politics and bureaucracy thus became centers of societal change. Constitutional rule was the first political demand from the 'left' (relative to the political scale of the time) all over Europe, and its fundamental issue was to get rid of 'despotism' in the form of monarchic rule through bureaucracy. This demand meant to give a decisive influence to elected bodies at least in fiscal and educational matters. It became usual to contrast bureaucratic and political responsibilities.

In this situation, during the first half of the nineteenth century, a long-standing request for reform of the civil service was finally agreed to in several countries. In Germany, France, and Britain these demands led to results, and extensive reforms of their civil service took place (Mann, 1986/1993, Gillis, 1971; Charle, 1980; Thuillier, 1980; Campbell, 1955; Mackenzie and Grove, 1957). These reforms had as their main objectives to reduce or get rid of nepotism in the appointment of personnel and to abolish corruption in order to establish a certain independence and objectivity among bureaucrats. Those who have investigated these reforms have not contended that they were

entirely successful, but it is generally said that a huge improvement took place. Since these days West European bureaucracy has established a reputation for being normally impartial and honest.

During part of the nineteenth century when the ideas of economic liberalism flourished, state intervention was normally confined to a restricted area, although practice never conformed to theory. When the security of the state or vital interests of common nature to the whole society were at stake, the state should intervene. This meant that military purposes were generally excluded from the restriction for the state to engage in economic activities and also some public education for the supply of civil servants, and, in fact, common interests could be extended into new fields. In principle, however, the civil servants had to protect state interests through legal means, and the military had to protect such interests through means of force and violence. The bureaucracy in the strict sense thus was an instrument for a 'legal domination,' one of the forms of power acknowledged by Max Weber. During most of the nineteenth century bureaucracy was regarded with distrust by the liberal forces in Europe and America and its growth was seen as an evil. Conservatives, with another evaluation of law and legal forms, tended to appreciate bureaucracy as a counterweight to democratic rule and as a guarantor of equal treatment and long-term obligations of the state system. This did not imply, however, that conservatives generally were favorably inclined to any growth of bureaucracy but, rather, that they wanted it to be strong and limited.

What holds for the development of state bureaucracies in Europe and the United States is not valid for the European colonies. The European powers pursued another policy in their colonies, which were ruled almost entirely through bureaucracy. Real political bodies existed only in the 'mother' countries, and the bureaucrats in the colonies were responsible to the governments in their political center and, indirectly, to their political mandators. Political elements in the colonies were few, elected bodies had little or no influence on the administration, and, most important, administration and military power were closely united in terms of command and responsibility. For example, in India the heads of bureaucracy (the civil administration, Indian Civil Service) in each district were intertwined with the military forces in the districts. Although they were separate organizations they were used together, if required, in command and operations, and the military personnel was used to enforce the implementation of the regulations of the civil service. This system, only slightly different in the colonies of different European powers, was based on bureaucratic rule in the colony. Thus, it differed completely from what was tolerated in the colonial states at home, and it meant a bureaucratization, which was never only a legal domination but always also domination by violence.

At the close of the nineteenth century the economy of most European countries and North America started to grow rapidly after a protracted slump. Investments increased, and trade and industry grew. As shown by Jürgen Kocka, the structure of the industrial and commercial firms changed. Very big companies arose, and these companies met new organizational problems. The structure of the Siemens and Halske Company had been, earlier, one of a patrimonial type with an allegiance of the salaried employees to the owners directly. Their loyalty was ensured through bonuses and other benefits given on a personal basis from the members of the Siemens family. In the 1880s, a total reorganization took place. The Company replaced the family. General regulations were given instead of personal instructions from the leadership. Benefits were regulated and depended on the firm (Kocka, 1969). Although this may have been an unusually clear case, several other examples show that this type of impersonalized bureaucratization took place in many industrial and commercial enterprises during the late nineteenth and early twentieth centuries (Torstendahl, 1991) (*see* Business History).

Not only did bureaucratization get an inroad in each company but industries also started to organize themselves into federations both as employers and as producers and traders. Such employers' associations and industrial organizations were intended to give support to their members through a general knowledge of industries and branches. This required an administrative staff. In this way private sector enterprises, both as individual firms and as organizations of firms, took a decisive step into a formal bureaucratization of their activities in the late nineteenth or early twentieth century. Thereby they also forced the states to act. It was impossible for states to rely only on their traditional administration, when organizations of industry made demands on the state and its policy.

States had to engage competent personnel, in the first place technically educated persons who could meet the demands from industry and trade. These new bureaucrats should also assist states in their demands on industry, initially in questions of security – inspectors of ships, elevators, constructions, bridges, railroads, etc. were engaged and organized into new administrative units. Security of labor became another source of state activity (Winkler, 1974; Bruguière et al., 1985; Torstendahl, 1991). Voluntary organizations and, not least, parties were also drawn into the organizational mainstream and got a bureaucratic structure (Michels, 1911).

It is well known that World War I (*see* First World War, The) meant an enormous growth of state intervention in the economy all over Europe. In order to make resources suffice for the most urgent needs the state had to regulate vast areas of the economy entailing an extensive bureaucratization. After the war most of the new administrations were abolished. The recollection of the war years and the large-scale bureaucratization of society during these years was, however, alive with many people, and it formed a source of inspiration to some both on the left and the right (Rials, 1977).

The reshaping of Europe after World War II (*see* Second World War, The) brought a new stage to bureaucratization: the social welfare administrations. They were foreshadowed in Scandinavia and France before the war but became a general phenomenon in West Europe only after the war. States then took the lead in the economies of European societies and, with or without nationalization of industries, wanted to carry through extensive planning. The variations between West European states were considerable in regard to political will. Enthusiasm for planning and welfare was great in the socialist and social democratic camps in countries like France, Britain, and Sweden (Rousso, 1986, 1987; Morgan, 1984) (*see* Socialism: Historical Aspects). In Germany and Italy, for a long period dominated by their Catholic and conservative parties, governments also accepted some state intervention (Baring,

1982; Mammarella, 1985), accentuated with political change in the late 1960s. All over Western Europe administrations grew in size and importance.

Around the end of the 1960s complaints about bureaucratization had become numerous, and bureaucracies had begun to behave independently of politicians, no longer implementing political demands but presenting more and more of their own policies (Aberbach et al., 1981; Mayntz and Scharpf, 1975). This new phase of bureaucratization meant that politicians began a drive to reduce the influence of bureaucracy on policy making. The cutting up of big administrations became usual in Europe, and efforts to strengthen the influence of politicians in relation to bureaucracies were frequent in the 1970s and 1980s. Curtailed bureaucracies, however, showed their tenacity through branching off and reestablishing at a local or regional level. Political initiatives may have been transferred more to the politicians, but in pursuing their policy politicians were dependent on negotiations with different interest groups and different bureaucratic bodies within the public sector. In the new negotiating economy bureaucracies played a distinctive role, although mostly in the background or as participants in the groups forming policy solutions in complete packages. Bureaucratization was no longer as obvious as earlier, but it did not mean that its development was reversed (Torstendahl, 1991).

Outside of Western Europe strong presidential systems have often given rise to a process of bureaucratization different from the one in Western Europe. In the United States the president is regarded as the head of the administration as well as the head of politics, while in Western Europe the two spheres have in principle been kept apart. Bureaucratization in Europe has meant that the superiority of politics over administration has been challenged through bureaucratic expansion, while in the United States bureaucratization has meant, rather, the increasing influence of federal (public) decisions in the private sector of economy and life, balanced by the equally strong judicial sector. Strong presidential systems have arisen in many other countries in the period after World War II but often without the strong judiciary that exists in the United States. Russia is one recent example.

The parallelism of the development of bureaucratization in Europe and North America, and in the twentieth century also Australia and New Zealand, thus became less visible after around 1950. Russia, on the other hand, has not done away with large parts of its bureaucracy from Soviet times after *perestroika* starting in 1985, which might have been expected. The strong presidential rule in new Russia relies heavily on the administrative organs, and these are still intertwined with the leadership of the privatized huge industrial conglomerates. In domestic matters the president is regarded and seems to regard himself more as the leader of an administration than as a political leader, and he has no party to rely on. The Duma and the Federation Council (and their predecessors in the previous constitution) have little influence over the government and the administration. Bureaucratic rule is still prevailing, as in Soviet and Czarist times (Shevtsova, 1999, 2005).

In the first decade of the twenty-first century the discussion over public administration and managerialism has been lively, but the term bureaucratization has become rare. Different schools of thought stand against one another: new public management (NPM) advocates hierarchy and efficiency (Pollitt and Bouckaert, 2011) in a so-called neo-Weberian state, while public value management has launched ethics and integrity as rivals to efficiency and economic criteria (Moore, 2005). Further, a participatory model has been put forward as a major alternative to NPM (Gay, 2010: Chapter 10). Ultimately, this debate is concerned with the relation between bureaucracy, democracy, and welfare, and the idea of representative bureaucracy has become important (Raadschelders, 2003). However, the whole debate is concerned only with bureaucracy in the democratic states of the present world. Globally other varieties exist, and the links to the past are different.

Bureaucratization as a General Phenomenon and Object of Theory Making

The interest in the problem of bureaucratization seems to have been directly dependent on the relation between politics and administration. With regard to the interest in bureaucracies surprisingly few books have been devoted to the process of bureaucratization as a general phenomenon (primarily Jacoby, 1969; Rizzi, 1939).

A wide literature has been produced on the bureaucratization of different parts of modern Western societies. Eisenstadt, with several investigations on bureaucratic developments, gave an overview of the literature in 1958, now somewhat outdated (Eisenstadt, 1958). A general approach has been tried in regard to the bureaucratization of socialism (Hodges, 1981), but most discussions of bureaucratization have been particular in regard to the selection of societies and time periods discussed.

Max Weber brought forward the basic criteria for a discussion of bureaucratization as a social phenomenon, answering to the need for rationalization in the sphere of government. His standpoint is often rendered as an inevitability of bureaucratization and an impossibility to evade the 'iron cage' of bureaucracy. This hardly does justice to Weber's sophisticated argument about men's possibility to counteract what seem to be probable predictions (Mommsen, 1974, 1989; Schluchter, 1989). However, several critics of contemporary culture in post-World War II Europe and America have taken bureaucratization as their point of departure for a demand to change a development into a civilization run by administration.

Abstract

This article contains a brief biography of the British cultural historian Peter Burke, and an outline of his very diverse and extensive publications, which focus principally on early modern Europe but sometimes stray backward to the late Middle Ages and forward into the nineteenth and twentieth centuries. Burke is especially well known among social scientists for his textbook on *Sociology and History*, revised under the title *History and Social Theory*.

Peter Burke (1937–) is a distinguished, wide-ranging, and highly productive British cultural and social historian. His specialist area is early modern Europe, although his writing is not narrowly confined to that. He is noted for his command of and research in several European languages – Latin, French, Italian, Spanish, Portuguese, Dutch, and German – and also for his extensive knowledge of social theory, on which he frequently draws in his writings. Social scientists are likely to be especially aware of his textbook *Sociology and History*, first published in 1980 and subsequently revised and expanded in 1992 and 2005 under the title *History and Social Theory*.

Burke was born in London; his father was of Irish origin, but his mother was the daughter of Jewish émigrés from Eastern Europe. In his essay in intellectual autobiography (2009a), he recalls that, for reasons that are in retrospect not quite explicable, from quite early in his childhood he wanted to be a historian. From St Ignatius's College, a Jesuit grammar school in Stamford Hill, north London, at 18 years he won an Open Scholarship to St John's College, Oxford. But in 1955, conscription was still in force in the United Kingdom, and the college advised Burke to do his 2 years of National Service in the army before going up to university. He became a pay clerk – a private soldier, not an officer – in the Royal Corps of Signals, and was posted to Singapore, where he served for 19 months. He was attached to the multiethnic, mainly locally recruited, Singapore District Signal Regiment.

> To me, an innocent fresh from an English school, the world of the regiment was excitingly scandalous. Everything was for sale. Drivers siphoned petrol out of their vehicles and sold it. Objects from the military stores turned up in the so-called 'thieves market' in the centre of town, offered for sale for a fraction of the official price.

The regiment, he writes, "bears some responsibility for making me into a particular breed of historian, fascinated by cultural encounters and misunderstandings and the distance between official and unofficial rules, a topic central to social history." Singapore also awakened an anthropological interest in other cultures.

Burke finally arrived in Oxford as an undergraduate in 1957, where he was tutored principally by Keith Thomas and the architectural historian Howard Colvin, and where he attended the lectures of other outstanding historians such as Christopher Hill, Lawrence Stone, Richard Southern, and John Hale. The Oxford history syllabus of those days was, he recounts, rather narrow, focusing predominantly on political and to a lesser extent economic history, with compulsory examination papers in English history and English constitutional documents. But Burke's interests were already turning to the social and cultural: he chose the Italian Renaissance as his third-year Special Subject, because "this was the only Special with room for cultural history." He spent his time reading Castiglione and Guicciardini – an anticipation of his lasting interest in the history of historical thought – and also recalls attending the inspirational lectures of the art historian Edgar Wind.

In 1960, having graduated with first-class honors, Burke moved to St Antony's College, then one of Oxford's newest, a postgraduate college with a mainly non-British student body. It was during this period that he began to be strongly influenced by the *Annales* school of historians, among them Lucien Febvre, Marc Bloch, and Fernand Braudel. He also began to take serious note of sociology, starting with attending a series of seminars on 'Alienation' – a topic much discussed in that period – organized by Norman Birnbaum and Iris Murdoch at Nuffield College. For his DPhil thesis, he chose to study the friar Paolo Sarpi's *History of the Council of Trent* (1619). The thesis, supervised by Hugh Trevor-Roper, was to have been entitled 'New trends in European historical writing, 1500–1700,' but it was never finished. Asa Briggs, who was just moving from the chair of history at the University of Leeds to become the founding Professor of History at the brand-new University of Sussex, gave a lecture in Oxford on sociology and history, and mentioned that Sussex was looking to recruit staff with interdisciplinary interests. Burke abandoned the DPhil and in the autumn of 1962 arrived in Sussex as an Assistant Lecturer in the School of European Studies.

During the next decade, Sussex's star burned brightly in the British intellectual firmament. Burke remembers that his first ever lecture was on Freud, as part of a course on 'The European Mind.' The sociologists Zev Barbu and Tom Bottomore; the art historian Hans Hess; the intellectual historians John Burrow, Stefan Collini, along with Donald Winch, Gabriel Josipovici, and Stephen Medcalf, were among Burke's friends and collaborators in a stellar interdisciplinary milieu that helped to shape his interests and career. By the late 1970s, however, the decline of university funding in Britain was beginning to take its toll at Sussex (as elsewhere), and Burke moved to Cambridge as a Fellow of Emmanuel College and as University Lecturer in History, eventually Professor of Cultural History. Since the 1970s, Burke has published at such pace that it is necessary to distinguish several interrelated strands: books reporting his

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61169-8

own substantive historical research, his historiographical writings, and his activity as editor and translator. Yet Burke did not publish his first learned article until he was 28, and his first 'substantial' book, *Culture and Society in Renaissance Italy* (Burke, 1972a), not until he was 35. As he points out, such dilatoriness would not now be possible in an age when young scholars are endlessly evaluated, with any failure to churn out a quota of publications always threatening to bring an end to their careers.

Nor had he, until his early thirties, worked in an archive. His earliest research had been based on printed sources. This too, for a historian, might now prove a serious obstacle to an academic career. The subsequent flood of books and essays from Burke's pen, many derived from archival research in several languages, shows how mistaken it may prove to be if artificial hurdles are erected for young scholars.

It was Tom Bottomore who invited Burke to write the first version of the series of books that are probably most widely familiar to nonhistorians. Appearing in 1980, *Sociology and History* – note the order of the words – can be seen in hindsight as marking the end of two decades in which sociology seemed an exciting new discipline that offered useful new ideas relevant to the work of several other university disciplines, notably history. Not that historians and sociologists always enjoyed the best of relations: as Burke wrote,

> In Britain at least, many historians still regard sociologists as people who state the obvious in a barbarous and abstract jargon, lack any sense of place and time, squeeze individuals into rigid categories and, to cap it all, believe that these activities are 'scientific'. Sociologists, for their part, see historians as amateurish myopic fact-collectors without a method, the vagueness of their data matched only by their incapacity to analyse them.
>
> 1980: 14

Burke stressed that he was facing two ways, addressing professions and writing about major contributors to each discipline for the benefit of the other. On the one hand, his book makes a powerful case for the relevance of the ideas of social and cultural theorists past and present to the practice and writing of history, ideas that met with resistance from an older generation of more traditional professional historians. On the other hand, less explicitly but no less convincingly, it demonstrates what the discipline of sociology has lost through what Norbert Elias (2009) called its 'retreat into the present' or what Goudsblom (1977) termed 'hodiecentrism.'

This masterly little book – it contained only just over 100 pages of printed text – opened with a chapter that sketched the major landmarks in the growth since the Enlightenment of a historically orientated sociology and a socially orientated history, in both Europe and the Americas. The longest of the three chapters was entitled 'Social Structures,' and introduced some key ideas: the comparative method; history, models, and types; survey analysis (including by historians); structure and function; social role; socialization, deviance, and control; social class and social stratification; social mobility; bureaucracy; patrons, clients, and factions; and mentality and ideology. The third chapter, on 'Social Change,' was constructed upon discussions of Herbert Spencer's and Karl Marx's models, and concluded with a consideration of 'four monographs in search of a theory.' These were Fernand Braudel's *The Mediterranean and the Mediterranean World in the Age of Philip II* (1972[1949]), William H. McNeill's *Europe's Steppe Frontier* (1964), Emmanuel Le Roy Ladurie's *The Peasants of Languedoc* (1974), and Nathan Wachtel's *Vision of the Vanquished* (1977), a study of the Spanish conquest of Peru that is perhaps now a little less widely known than the first three. All four monographs, it will be observed, are by historians, and, though he certainly faced two ways, this confirms that Burke was a little more concerned with explaining the value of sociological ideas to his fellow historians than with stressing the necessity of historical perspectives for sociology.

When Burke was invited, by a different publisher, to produce a revised and significantly enlarged second edition (and later a third) of the book, it appeared under the new title of *History and Social Theory* (1992). He had originally subsumed a good deal of social anthropology under the umbrella term 'sociology,' which reflected the fact that until the 1980s the sociological syllabus in British universities – and perhaps to a lesser extent in the United States – had always drawn a good deal upon anthropological studies. The original book had also said a little about economics and political science too. By the 1990s, however, there had been a veritable explosion of 'theory' across the board of the humanities and social sciences. As Burke remarked,

> a discussion of social theory might reasonably be expected to include much more, including such disciplines or sub-disciplines as communications, geography, international relations, law, linguistics (especially socio-linguistics), psychology (especially social psychology) and religious studies. It is also virtually impossible to exclude interdisciplinary enterprises such as critical, cultural and feminist theory, or indeed philosophy (which might be defined as the theory of theory).
>
> 1992: vii

Burke does not say so, but the changed title may be taken also to reflect the diminished scope of the discipline and the word 'sociology,' which has gradually lost the encompassing general meaning of 'the study of society,' and become one social science among many. More disturbingly, despite the renewed vigor of 'historical sociology' in recent decades, that has been a minority trend; the broader trend in the sociological profession has been toward what Burke would hope to have countered: an increasingly present-centered, ahistorical, and technicized discipline.

If the 1980 book reflected the preoccupations of sociological theory in the 1960s and 1970s, the two later versions incorporate many of the developments and the writers who rose to prominence in various disciplines in the subsequent decades. Much of the original text remained, but it was radically reorganized and supplemented. For instance, by 1992 the four monographs had become six, and now included Norbert Elias's *On the Process of Civilisation* (2012[1939]), Michel Foucault's *Discipline and Punish* (1977), and Marshall Sahlins's *Islands of History* (1985). Figures such as Clifford Geertz and Pierre Bourdieu received much greater attention. By 2005, the 'cultural turn' in social theory was recognized in fuller discussions of Bakhtin and Gombrich (T.S. Kuhn makes a surprisingly delayed appearance too), and of Pierre Bourdieu who by then had become the world's most cited sociologist. In face of

the avalanche of theoretically significant writing, the six monographs now disappear, but are replaced by a whole concluding chapter on 'Modernity and Postmodernism,' with discussion of globalization and the development of a global history that begins to surmount the Eurocentrism of the past.

Burke as a historian displays a breadth of knowledge and theoretical command that would be the envy of most specialist 'theorists' in sociology. What is possibly more impressive is the broad tolerance he exhibits toward so many varieties of 'theory.' Most specialists feel the need to favor some and reject other varieties. Some of what is called 'theory' is widely seen among social scientists as philosophoidal pretension with little relevance to the conduct of historical or social scientific research, and often redescribing old problems with new jargon. What seems to enable Burke to show such broad sympathies and tolerance is that over the course of all three editions of his book, he has filtered out and retained precisely the ideas that have relevance to the writing of history. And writing history has always been, to put it colloquially, Peter Burke's 'day job.'

Culture and Society in Renaissance Italy (Burke, 1972a) was an instance of the prosopographical method, focusing on 600 artists and humanists of the Italian Renaissance. The method, which involves using a great many only partially known biographies to establish a collective picture of the life of members of a group, had been championed a year earlier by Lawrence Stone in an influential article (1971), but the work of Sir Lewis Namier on eighteenth-century parliamentarians (1957[1929]), Francis Haskell's on patronage and taste (1963), as well as the writings of Arnold Hauser (1951–62, 1982) and Raymond Williams (1958) were prior influences. Prosopography as a historical method is also analogous in a limited way to survey research in sociology.

Prosopography continued in Burke's first thoroughly archival project, *Venice and Amsterdam* (1974), a comparison of the two cities' patricians in the long seventeenth century, 1580–1720. Both were rich mercantile cities dominated by merchant elites, rather than the warrior and subsequently courtly nobility found in the larger western European states. The Amsterdam *Regenten* were commoners, while the Venetian patricians were noblemen, although Burke notes that the Venetian elite's style of life resembled not that of *noblesse de l'épée* but that of the *noblesse de robe*, or even of the Chinese mandarins (1974: 62). Both lived in their cities rather than on country estates, although later in the eighteenth century both tended to be transformed into rentiers.

This book also led later to a small but interesting offshoot, a study of Antwerp (1993a) in its brief period of world significance, roughly the first six decades of the sixteenth century. Its dominance followed that of Venice, and was succeeded by that of Genoa and Amsterdam. After that, what Braudel termed 'world economies' were not cities but nation-states. The comparative sweep of this short book is striking: the chapter on 'centers of painting' discusses Florence, Venice, Rome, Antwerp, Amsterdam, and Paris, as well as the lesser centers of Nuremberg and London. Chapters follow on 'centers of performance,' dealing with public and private rituals as well as theaters, 'centers of printing,' and finally a study of three Asian cities, Istanbul, Peking, and in Japan the Kyoto/Osaka/Edo complex. Burke concludes that what makes a city a cultural metropolis is absence of censorship, more centralized states (especially the deracination or courtisation of the warrior nobility), and economic prosperity.

After *Venice and Amsterdam*, Burke turned his attention from elite to popular culture. This book displayed a tendency he later identified as a characteristic of his career, that the choice of a research topic for the next one "in some sense compensated for what was lacking in my earlier work" (2009a: 276). *Popular Culture in Early Modern Europe* (1978) was also influenced by Burke's 'discovering (belatedly) the work of Edward Thompson,' and a growing friendship with Raphael Samuel and involvement in the History Workshop movement. One of Burke's key theses was that until Renaissance, European elites were 'bicultural' or 'amphibious': they participated in popular culture as well as high culture. At the close of the Middle Ages, popular culture was everyone's culture, in the sense that the educated participated in it as a second culture and it was the only culture for everyone else. Peasant and priest, artisan and noble shared to a significant extent a common culture of intellectual and religious interests, moral and political assumptions, but over the next three centuries this common ground dwindled very markedly. Printing was a powerful force promoting the withdrawal of the upper classes from popular culture. There was a sharpening of boundaries between city dwellers and peasants, and between the educated urban elite and the illiterate urban laborer. This happened in part because the effect of wider literacy, amplified by printing, made it possible for the literate, learned culture to evolve far more rapidly than the traditional culture of the less educated classes. Printing also very much facilitated the process of social emulation of the habits, styles, and interests of one class or stratum by another, yet it should not be thought that printing led to rapid cultural homogenization. In early modern Europe it reduced certain social divisions but enhanced others. Today, many boundaries are being eroded, but, as Burke notes, "there is now a danger of underestimating the importance of cultural boundaries in the past" (1978: 9 (third ed.)).

Thus far, Burke had never made politics central to his writings – a prolonged reaction perhaps to its overprominence in the traditional history that prevailed in his student days in Oxford – and *The Fabrication of Louis XIV* (1992a) was in part intended to compensate for that. The topic of the construction of Louis XIV's image combined politics with culture. The first draft was written at the Wissenschaftskolleg in Berlin in 1989–90, a time and place when politics was inescapable, and the book is notable for its comparisons of official image making in the seventeenth and twentieth centuries. Loosely linked to *Fabrication* by the subject matter of courts and courtiers was Burke's book *The Fortunes of the Courtier* (1995), a study of the Europe-wide impact of Castiglione's *Il Cortegiano*.

One whole group of Burke's books is that concerned with the social history of language. *The Art of Conversation* (1993b) brought together essays by Burke on language early modern Europe: postmedieval Latin; language and identity in Italy; the art of conversation in early modern Europe; and the social history of silence. There followed *Languages and Communities in Early Modern Europe* (2004), in which he explores the social and cultural history of the languages spoken or written in Europe between the invention of printing and the French Revolution, arguing that, from a linguistic point of view, 1450 to 1789

should be regarded as a distinct period. One major theme of the book is the relation between languages and communities (regions, churches, occupations, and genders, as well as nations) and the place of language as a way of identifying others, as well as a symbol of one's own identity. A second, linked theme is that of competition: between Latin and the vernaculars, between different vernaculars, dominant and subordinate, and finally between different varieties of the same vernacular, such as standard languages and dialects. But Burke's own writings on language have to be considered along with numerous books that he has edited, notable among them three important volumes in collaboration with Roy Porter (1987, 1991, 1995). His introduction to the first of these begins, "It is high time for a social history of language, a social history of speech, a social history of communication. In the last generation or so, as the rise of feminist and regionalist movements shows, dominated groups have become more sharply aware of the power of language as well as the involvement of language with other forms of power." In the third volume, his essay on 'The Jargon of the Schools' demonstrates how far back goes the accusation that 'unintelligibility is at a premium' among intellectuals staking out their territory through the use of their own jargon. A fourth volume, *Cultural Translation in Early Modern Europe* (2007), was edited with R. Po-chia Hsia. Burke's own paper there is concerned with translations from the vernacular languages into Latin; as he remarks, that seems counterintuitive – translation in the 'wrong' direction – but it was not unusual.

Burke answered his own call for a 'social history of communication' in a two-volume work of his own and another coauthored with Asa Briggs. Together, the two volumes of *A Social History of Knowledge* (2000–12) are perhaps Burke's most ambitious project to date. The first, subtitled *From Gutenberg to Diderot*, is firmly in his own early modern territory, but in the second, *From the Encyclopédie to Wikipedia*, he has been 'eased out' of that familiar landscape. He notes that he began the work consciously in the tradition of Karl Mannheim and the sociology of knowledge. Topics covered in the book include the 'establishment' of knowledge in institutional arrangements such as academies, centers and peripheries in the location of knowledge (the idea of center and periphery being a recurrent theme in Burke's writings), the control of knowledge by churches and states, and the sale of knowledge through markets and the press. The final chapter of the first volume concerns 'trusting and distrusting knowledge,' and concludes with a quotation from Mannheim: "Basically, it was in political struggles that for the first time men became aware of the unconscious motivations which had always guided the direction of thought …. The discovery of the social-situational roots of thought first, therefore, took the form of unmasking" (Mannheim, 1936: 35).

In between those two volumes appeared *A Social History of the Media* (Briggs and Burke, 2002). Burke was primarily responsible for the first three chapters – the Introduction, The Print Revolution in Context, and The Media and the Public Sphere in Early Modern Europe – and Briggs for the later period, but the two authors read, revised, and took joint responsibility for all chapters.

One other book in which Peter Burke journeys beyond his early modern homeland is *Cultural Hybridity* (2009b), which takes its departure from a remark by Perry Anderson (1998) that we live in a postmodern age in which intersections, hybridity, potpourri are esteemed. Burke recognizes that today we live in era of 'culture wars' in which there is conflict over precisely such cultural hybrids.

Besides his many works of substantive history, Peter Burke has written very extensively on matters of historiography. His very first book, which he does not deign to mention in his essay in intellectual autobiography, was *The Renaissance Sense of the Past* (1969). An opening chapter on 'Medieval historical thought,' in which he shows that medieval historians, besides taking the Bible as an unquestionable source, lacked a sense of the past being different in quality from the present, resulting in what would later seem incongruous anachronisms in their writings. And their attitude toward evidence was uncritical, so that medieval history writing is full of myths, secular and religious. The body of the book then traces the emergence of a 'sense of the past' through among other things the antiquarian movement, developments in the law, and the critical study of documents, culminating in a look forward 'Towards a sociology of historiography.' *The Renaissance* (1987) too is essentially historiographical, charting modern historians' view that the European Renaissance of the fifteenth to seventeenth centuries was neither historically unique nor so abrupt a departure from the medieval period as Jacob Burckhardt (1860) depicted it. It was more a movement than a period. *Eyewitnessing* (2001) is concerned with the use of images as historical evidence. One striking point that it makes is related to the discussion of anachronism in the much earlier *Renaissance Sense of the Past*: that painters, unlike historians, could not dodge the question of whether to dress their subjects in a historically accurate way or in the style of their own day.

Throughout his career, Peter Burke has felt an affinity with the *Annales* school. He wrote a history of the school (1990), but, as editor and translator, has also contributed mightily to making the work of the French historical school better known in the Anglophone world. In *A New Kind of History* (1973), he made available several of the most important essays by Lucien Febvre who, despite being the founder of the school along with Marc Bloch, and in particular the champion of the idea of *mentalités* as one of its central objects of study, had remained until then somewhat less familiar in English than Bloch and the next generation of *Annalistes*. *Economy and Society in Early Modern Europe* (1972b) presented essays published in the *Annales Économies–Sociétés–Civilisations* in the period 1955–66, by inter alia Fernand Braudel, Carlo Cipolla, and Emmanuel Le Roy Ladurie. Burke's French connection is also seen in his edition of a collection of critical writings on Michel Foucault (1992b) who, though his origins lay in philosophy and though he was not exactly a member of the *Annales* school, had an immense impact upon the writing of history that would not have been possible without the prior influence of the school. A final editorial contribution to historiography is *New Perspectives on Historical Writing* (1991), which contains a catholic selection of contributions on history from below, women's history, overseas history, microhistory, oral history, history of reading, visual history, history of political thought, history of the body, and environmental history. Burke's own final chapter is on 'History of Events and the Revival of Narrative' (1991: 283–300). The recognition that, in the end,

events still matter is further evidence of the breadth of Burke's historical vision. Too often 'history from below' and the 'history of events' – especially the kind of narrative of national political events that once monopolized the school and undergraduate syllabuses – have been set up as mutually exclusive opposites. But events – the reigns of kings and queens, wars, battles, and political conflicts – have lasting social and cultural consequences that cannot be ignored by the social and cultural historian.

In fitting conclusion, it should be mentioned that Burke, together with his wife Maria Lucia Pallares-Burke, has written a major study (Burke and Pallares-Burke, 2008) of the Brazilian intellectual Gilberto Freyre (1900–87). It is fitting because Freyre was also a multifaceted thinker who is difficult to pigeonhole. Wikipedia has described him as "sociologist, anthropologist, historian, writer, painter, journalist and congressman." Peter Burke has never served in parliament, does not write much for newspapers, nor so far as we know does he paint; but in their range his writings qualify him as 'sociologist, anthropologist, historian, writer,' and he has spent a good deal of time studying painters too.

Abstract

Burnout is a psychological syndrome that develops in response to chronic emotional and interpersonal job stressors. The three defining components of this syndrome are (1) exhaustion, (2) cynicism and detachment from the job, and (3) a sense of inefficacy and reduced accomplishment. Burnout impairs both personal and social functioning. While some people may quit the job as a result of burnout, others will stay on, but will only do the bare minimum rather than their very best. This decline in the quality of work and in both physical and psychological health can be costly – not just for the individual worker, but for everyone affected by that person. Consequently, there has been a growing interest in developing interventions to reduce burnout, from government agencies and organizations in both the public and private sectors.

A Brief History of Burnout Research

Although the birth of the burnout concept, as we know it today, began in the 1970s, that does not mean that the problem itself suddenly burst on to the scene at that time. The relationship that people have with their work, and the difficulties that can arise when that relationship goes awry, have been long recognized as a significant phenomenon in people's lives. Earlier writing, both fictional and nonfictional, described similar phenomena, including extreme fatigue and the loss of idealism and passion for one's job. Perhaps the clearest example is Greene's 1961 novel, *A Burnt-Out Case*, in which a spiritually tormented and disillusioned architect quits his job and withdraws into the African jungle. It is probably fair to say that burnout had been identified as a problem by both social commentators and practitioners long before it had a recognized name and had become a focus of systematic study by researchers.

And it was the identification of that name, 'burnout,' which has such evocative power to capture the psychological reality of people's experiences in the workplace, which occurred in the 1970s. The origins of its usage are somewhat murky, but appear to come from the illicit drug scene, where 'burnout' referred to the physical effects of chronic drug abuse. Counselors and therapists who worked with drug addicts borrowed the term to describe their own psychological deterioration and stress. This use of 'burnout' was reported by a clinical psychologist, Herbert Freudenberger (1974), in a volume of articles about free clinics. At that same time, a social psychologist, Christina Maslach, was conducting exploratory research with workers in health care and human service occupations, studying how they coped with strong emotional arousal on the job. During the course of the interviews, some of the workers described their psychological difficulties as 'burnout,' and Maslach shifted her focus to describe this phenomenon (1976). For both Freudenberger and Maslach, burnout was rooted within caregiving and service occupations, in which the core of the job is the relationship between provider and recipient. This interpersonal context of the job meant that, from the beginning, burnout was studied not simply as an individual stress response, but in terms of an individual's relational transactions in the workplace. Moreover, this interpersonal context focused attention on the individual's emotions, and on the motives and values underlying his or her work with other people.

The clinical and social psychological perspectives of the initial articles influenced the nature of the first phase of burnout research. On the clinical side, the focus was on symptoms of burnout and on issues of mental health. On the social side, the focus was on the relationship between provider and recipient, and on the situational context of service occupations. Most of this initial research was descriptive and nonempirical – it was more qualitative in nature, using such techniques as interviews, case studies, and on-site observations. In addition, this first phase was characterized by a strong applied orientation, which reflected the particular set of social, economic, historical, and cultural factors of the 1970s. Both Farber (1983) and Cherniss (1980) provided analyses of how these factors had influenced the professionalization of the human services in the United States, and had made it more difficult for people to find fulfillment and satisfaction in these careers. Burnout workshops became a primary mode of intervention, as exemplified in the work of Pines et al. (1981).

A second phase of burnout research developed in the 1980s, in which the emphasis shifted to more systematic empirical research. This work was more quantitative in nature, using questionnaire and survey methodology, and studying larger subject populations. A particular focus of this research was the assessment of burnout, and several different measures were developed. The scale that has had the strongest psychometric qualities and has been used in over 90% of the research studies is the Maslach Burnout Inventory (MBI) developed by Maslach and Jackson in 1981.

The shift to greater empiricism was accompanied by theoretical and methodological contributions from the field of industrial–organizational psychology. Burnout was viewed as a form of job stress, with links to such concepts as job satisfaction, organizational commitment, and turnover. The industrial–organizational approach, when combined with the prior work based in clinical and social psychology, generated a richer diversity of perspectives on burnout and strengthened the scholarly base via the use of standardized tools and research designs.

Another aspect of this empirical phase is that burnout extended beyond its original American borders. At first, the phenomenon drew attention in English-speaking countries, such as Canada and the United Kingdom. Soon articles, books, and research measures were translated into numerous languages, and subsequently research on burnout emerged in many countries of Europe, as well as Israel. By the 1990s, the intellectual contributions of European authors in terms of theory, research, and intervention were considerable (most notable is the work of Schaufeli and his colleagues; see Schaufeli et al., 2001; Schaufeli and Enzmann, 1998). Now, in the twenty-first century, burnout research is even more global, and is being done in many countries around the world. As a result of all these new contributions, the concept of burnout has been extended to occupations beyond the human services and education, and burnout research has been enhanced by more sophisticated methodology and statistical tools, as well as new structural models.

Defining and Understanding Burnout

Burnout research was exploratory at first, very bottom-up and anchored in people's experiences. As studies began to show a clearer pattern of the burnout phenomenon, it became possible to establish it as a prolonged response to chronic interpersonal stressors on the job. The three key dimensions of this response are an overwhelming exhaustion; feelings of cynicism and detachment from the job; and a sense of ineffectiveness and lack of accomplishment. The exhaustion component represents the basic individual stress dimension of burnout. It refers to feelings of being overextended and depleted of one's emotional and physical resources. The cynicism (or depersonalization) component represents a motivational, interpersonal distancing dimension of burnout. Depersonalization refers to a negative, callous, or excessively detached response to various aspects of the job; cynicism refers to losing an emotional or cognitive involvement with work. The component of reduced efficacy or accomplishment represents the self-evaluation dimension of burnout. It refers to feelings of incompetence and a lack of achievement and productivity in work.

These three dimensions of burnout are assessed by the MBI (see Maslach et al., 1996, for all versions of the measure, which has been translated and validated in many languages). Recently, an alternative burnout questionnaire has been proposed – the Oldenburg Burnout Inventory – that assesses the two dimensions of exhaustion and disengagement from work (Halbesleben and Demerouti, 2005), and has shown high convergent validity with the MBI. Other conceptualizations of burnout have considered exhaustion to be the sole defining criterion (Freudenberger, 1983; Pines et al., 1981). Although more recent theories make distinctions between various aspects of exhaustion – e.g., physical fatigue, emotional exhaustion, and cognitive weariness (Shirom and Melamed, 2005) or physical and psychological exhaustion (Kristensen et al., 2005) – their measures inevitably produce a single overriding factor of exhaustion. However, the fact that exhaustion is a necessary criterion for burnout does not mean it is sufficient. Exhaustion is not something that is simply experienced – rather, it prompts actions to distance oneself emotionally and cognitively from one's work, presumably as a way to cope with the work overload. Distancing is such an immediate reaction to exhaustion that a strong relationship from exhaustion to cynicism is found consistently in burnout research, across a wide range of organizational and occupational settings.

Three decades of burnout research conducted at the individual level of analysis has resulted in a deep understanding of how individual employees react to their jobs. The exhaustion component of burnout is more predictive of stress-related health outcomes than the other two components. These physiological correlates mirror those found with other indices of prolonged stress. In terms of mental health, the link with burnout is more complex. It has been assumed that burnout may result in subsequent mental disabilities, and there is some evidence to link burnout with greater anxiety, irritability, and depression. However, an alternative argument is that burnout is itself a form of mental illness, rather than a cause of it. Some of this research has focused on the distinction between burnout and depression: burnout is job-related and situation-specific, as opposed to depression, which is general and context free. Other research has established clinical burnout as the equivalent of work-related neurasthenia (Schaufeli et al., 2001).

Some of the burnout research has considered a range of personal qualities. Burnout scores tend to be higher for people who have a less 'hardy' personality or a more external locus of control, or who score as 'neurotic' on the Five-Factor Model of personality. People who exhibit Type A behavior tend to be more prone to the exhaustion dimension of burnout. There are few consistent relationships of burnout with demographic characteristics. Although higher age seems to be associated with lower burnout, it is confounded with both years of experience and with survival bias. The only consistent gender difference is a tendency for men to score slightly higher on cynicism.

Burnout has been associated with various forms of job withdrawal – absenteeism, intention to leave the job, and actual turnover. However, for people who stay on the job, burnout leads to lower productivity and effectiveness at work. Consequently, it is associated with decreased job satisfaction and a reduced commitment to the job or the organization. People who are experiencing burnout can have a negative impact on their colleagues, both by causing greater personal conflict and by disrupting job tasks. Thus, burnout can be 'contagious' and perpetuate itself through informal interactions on the job. There is also some evidence that burnout has a negative 'spillover' effect on people's home life.

Much of the burnout research has found that social and organizational conditions are the primary correlates of burnout across many occupations (see reviews by Maslach et al., 2001; Schaufeli and Enzmann, 1998). These factors can be summarized within six key domains of the workplace environment: workload, control, reward, community, fairness, and values. The first two areas are reflected in the Demand–Control model of job stress (Karasek and Theorell, 1990). Work overload occurs when job demands exceed human limits. People have to do too much in too little time with too few resources. Increased workload has a consistent relationship with burnout, especially with the exhaustion dimension. Control includes employees' perceived capacity to influence decisions that affect their work,

to exercise professional autonomy, and to gain access to the resources necessary to do an effective job. A major control problem occurs when people experience role conflict. Reward refers to the power of reinforcements (monetary, social, and intrinsic) to shape behavior. Insufficient reward and lack of recognition increases people's vulnerability to burnout by devaluing their work and increasing their feelings of inefficacy. Community is the overall quality of social interaction at work, including issues of conflict, mutual support, closeness, and the capacity to work as a team. When these workplace relationships lack support and trust, or are characterized by incivility and unresolved conflict, then the risk of burnout is higher. Fairness emerges from the literature on equity and social justice, and refers to whether people feel they are being treated fairly and with respect. Burnout is more likely when people perceive the workplace to be characterized by inequity, lack of reciprocity, and an effort–reward imbalance. Finally, values are the ideals and motivations that originally attracted people to their job, and thus they are the motivating connection between the worker and the workplace, which goes beyond the utilitarian exchange of time for money or advancement. When there is a value conflict on the job, and thus a gap between individual and organizational values, workers will find themselves making a trade-off between work they want to do and work they have to do. Research has found that a conflict in values is related to all three dimensions of burnout.

A consistent theme throughout this research literature is the problematic relationship between the individual and the situation, which is often described in terms of imbalance or misalignment or misfit – for example, the demands of the job exceed the capacity of the individual to cope effectively, or the person's efforts are not reciprocated with equitable rewards. Some of the earliest models of organizational stress focused on this notion of job–person fit, which was assumed to predict less strain and better adjustment, and subsequent theorizing continued to highlight the importance of both individual and contextual factors (see Kahn and Byosiere, 1992). A mediation model of burnout focuses on the degree of perceived match, or congruency, between the individual and the six key areas of the workplace environment listed above. When there is greater mismatch between the person and the job, there is a greater likelihood of burnout, which in turn predicts work-related outcomes (Leiter and Maslach, 2005). In other words, burnout appears to be the mediating state between work stressors and work outcomes (see **Figure 1**). It is not simply that burnout is an important psychological outcome in its own right, but that it is related to people's commitment to their work and their motivation to perform well on the job.

Figure 1 The mediation role of burnout.

Research on Burnout Interventions

This analysis of the burnout phenomenon points to an important bottom line in terms of the fit between people and their job. Employees need to have some choice and control over how they handle their workload, some sense of recognition and reward, support from the people they work with, and a sense of being treated with respect and fairness. There must be effective ways to resolve conflicts, and there should be clear organizational values that can mesh with employees' personal motives. All workers want to know that they are doing meaningful work that makes them proud. Burnout can be prevented and reduced when employers design workplaces that engage employees, and employees have the opportunity to make job choices that match their personal attributes. These guidelines may seem fairly simple and straightforward, but putting them into practice can be a complex process that requires continuous time and effort. However, the outcomes are well worth the commitment – healthier workers and more productive organizations.

Unfortunately, the work that has been done to test and evaluate the efficacy of burnout interventions has been fairly sparse over the years. Despite the public interest in finding solutions to the burnout problem, there are many obstacles and difficulties in actually doing the kind of work that would provide some clear answers to the question of "what can we do to deal with burnout?" Most burnout interventions have focused on changing or treating individual people, and have not dealt with the situational factors that have been identified in the research. Thus, there have been debates about whether to help people cope with stress, or to put them on disability leave and treat them for severe depression. Such debates reopen the issue about how to define burnout, almost as if there has not been over 30 years' of research on this topic. The clearest metamessage that comes from reviewing the literature on burnout interventions is that the significance of the work environment has been greatly underestimated, relative to the significance of the individual. Intervention efforts must underscore the necessity of understanding individual behavior in its social context. If future work does not address directly this issue of person–situation interaction, then true progress in the prevention of burnout is likely to be negligible.

A promising development in burnout research has been to expand the framework to the positive opposite of burnout, rather than just focus on the negative state that it represents. This positive experience has been called work engagement, and many studies are being done to further understand the personal and situational factors that promote greater engagement in the workplace (Bakker and Leiter, 2010). Such a framework leads people to consider what factors are likely to enhance employees' energy, vigor, and resilience; to promote their involvement and absorption with the work tasks; and to ensure their dedication and sense of efficacy and success on the job. The question for interventions, then, has been changed to "how do we build/enhance engagement with work" rather than "how do we reduce the occurrence of burnout." Focusing on job

engagement represents a new way of thinking about solutions to burnout.

In addition, burnout researchers have been developing new tools and paradigms that can be adapted to applied research on interventions, and have been developing better partnerships with practitioners and organizations in the search for effective solutions (Maslach et al., 2012). Moreover, a new international e-journal, *Burnout Research*, will provide a much-needed, dedicated venue for the publication and dissemination of cutting-edge research, critical reviews, and new translational research on promising interventions. Given the ongoing importance of the burnout phenomenon, and the rising interest in making real progress in alleviating it, there is a need for a primary place to capture the many contributions being made.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

This article is reproduced from the previous edition, volume 2, pp. 1418–1421, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

This article describes all the interfaces between a modern business organization and its surrounding community, for business success depends on meeting the requirements and demands of that community. Advertising market research, and public relations are all means of influencing and matching the requirements of the market. The application of business ethics, including concern for the physical environment, is a means of enhancing the social and economic standing of a business. Equally important is the use of up-to-date technological developments within the operation of a business, with sensitive awareness of their impact on industrial relations. At the same time, all businesses are affected by political processes introducing new laws and taxes, and by the changing structure of the population in age, balance between the sexes, and employment requirements. Each of these interfaces is examined in turn. Social accounting is more concerned with macroeconomics investigating how whole industries and institutions relate to the wider economy and society, and how the production of goods and services income formation, and income distribution relate to each other. Social accounting techniques have been widely applied in the fast developing economies of the third world.

To succeed, any modern business manager needs to understand all the interfaces between the business and wider society no less than all the internal operations of the business itself. For no business can survive, let alone flourish, unless it provides goods or services for which customers outside the business will be prepared to pay. Business success depends on meeting market demand. Awareness of market conditions and of how the market may be influenced is a key part of business management. In this article the various interfaces between businesses and their social context are briefly examined, using a form of analysis which has come to be known by the acronym SLEPT, in which the different letters stand respectively for the Social, Legal, Environmental, Political, and Technological factors influencing business organizations.

Social Factors

Market demand depends on the needs, desires, and interests of people in society, and knowledge of these is essential if a business is successfully to meet that demand. Such factors may be determined by the physical climate, by the language and culture, or by the demographic structure of a society. There is likely to be little demand, for example, for heavy overcoats in tropical countries, or for umbrellas in arid lands. In some cultural settings it is still rare for women to seek paid employment. In others the increase in life expectancy may have resulted in increasing demand for leisure activities for pensioners who have retired from employment. Changes to birth rates cause fluctuations in demand for goods and services required by children. These are examples of the ways in which knowledge of the market place will help a business entrepreneur to decide what goods to produce and offer for sale to meet demand.

Part of the cultural context of a business is the prevailing ethos or climate of moral opinion about what are right standards for business activity and trading. During the last two decades, such questions of business ethics have figured increasingly in public concern and on the agendas of business organizations. These highlight the need for complete probity and accountability in business, and for more openness in the operations of boards of directors (Carroll and Buchholtz, 2012). Ethical considerations may involve how a firm exploits its markets, how it obtains raw materials or cheap labour for its operations in different parts of the world, or how its activities affect the physical environment (which will be explored more fully in Section Environmental Factors).

The ethical standing of a business will affect its public relations, which in turn may impact upon the demand for its products, one way or the other. Modern businesses, especially larger ones, pay increasing attention to their public relations and how their images – and the brand images of their products – appear to the general public. Part of that public image is determined by how a business is presented by the news media, part by the reputation which products have among customers, and part by the business' own public advertising of its products. No successful business can ignore its need for a continual campaign to advertise its products, for in this way it can significantly influence market demand and maintain its share of markets with strong competition. The outlets for advertising are constantly spreading, using newspapers, magazines and journals, individual mail-shots, public hoardings, television and radio, and more recently, the Internet. This leads to the whole field of electronic commerce to be considered more fully in Section Technological Factors. At the same time, businesses need to be conducting market research, assessing public opinion about their existing products and exploring what other demands there are in the marketplace for potential new products. Market research enables a business to maintain direct links with any community where it seeks to trade.

The social factors relating to a business company have been recognized in many circles by introducing the concept of stakeholders of the company, who are all the groups of people with a legitimate interest in the operations of the company, not

just the shareholders. Stakeholders equally include the employees of a business, the customers, local residents and communities, and representatives of environmental interests (Carroll and Buchholtz, 2012). For many years there have been schemes of co-ownership and copartnership which have involved employees in the actual ownership of companies. More recently, and particularly in the United States, some corporations have introduced special constitutional features so that there are boards with representation from all stakeholder groups. A growing number of large firms are now publishing regular social or environmental reports as a means of accounting to all their stakeholders; and independent professional bodies are now issuing reviews of whole industries in this way, such as the Turnbull Report of the Association of Chartered Accountants of England and Wales. These arrangements vary in their levels of formality, but they are all attempts to involve wider social interests in the decision-making processes of the company. The growth of consumerism and of specific organizations established to protect and further consumer interests has inevitably brought increasing pressures to bear on the decisions of many businesses.

Legal Factors

The framework for business activity in any society may be constrained by legal requirements in that society. As long ago as 1570, the English Parliament enacted a law requiring every member of the 'lower classes' over the age of 6 years to wear a woollen cap on Sundays and holidays. Such legislation would today be regarded as a gross infringement of personal freedom, but it was introduced to further the interests of the politically powerful sheep farmers and wool traders at the time.

In later centuries in Britain there was significant dismantling of such legal constraints on business, with the ending of the mercantile system and the growth of '*laissez faire*.' Free market economists like Adam Smith, Thomas Malthus, David Ricardo, and John Stuart Mill advocated the freeing of business markets from legal restraint and control, so that the 'invisible hand' of free market forces could determine the price levels at which supply would equal demand. It was maintained that the interests of both producers and consumers were optimised by the free play of market forces, and that this required the absence of legal constraints, to enable businesses best to serve society by pursuing their own interests as vigorously as possible.

During the last 180 years, however, the political pendulum has swung very much the other way. Acts of Parliament in Britain ended the slave trade, banned the employment of women and children in coal mines, and introduced legislation for the health and safety of employees in factories and other places of work. Other statutes provided for the registration of business companies, giving them legal entity as corporate bodies rather than partnerships of all their various owners, and limiting the financial liability of shareholders to what they paid for their shares. Increasingly under governments of differing political shades, more and more legislation has come into force in virtually all countries of the world which sets the standards and requirements to be observed in business trading. Business managers need a very full awareness of the legal framework in which they are operating, both of the statutes established by political processes and of the decisions of courts in applying those statutes and developing case law.

Environmental Factors

Concern for the health and safety of employees is one example of a limitation on business operations to curb the potentially harmful effects of those operations. Just as people within the workplace may be injured and exposed to health risk, so too the activities of a business, in both production and distribution, may be detrimental to people living in the vicinity, along transport routes, and in the community generally. The discharge of waste materials from industrial processes, be they solid, liquid, or gaseous, on to waste land, into rivers, or into the atmosphere can have harmful effects reaching far into other countries, and into the ozone layer above the atmosphere. There is global concern that raw materials are being depleted at rates which will restrict or even exhaust their availability for future generations. For instance, the rain forests of Brazil are being decimated by the worldwide demand for timber and paper (Parker, 2011). Similarly, known reserves of fossil fuels in the world are finite. Public opinion is increasingly aware of the environmental effects of business activities in the widest contexts and longest timescales, and there is growing demand that all economic activity should be environmentally sustainable and without permanent damage to the planet.

Most goods supplied to the market today are packaged in some form, and difficulties may arise in the disposal of the packaging. Cardboard, paper, bottles, and some metallic containers can now be recycled for reuse, but containers made of some plastics have no future use. Manufacturers therefore need to be more aware of the environmental impact of the way they package their products. And in this age of the throw-away society, there are immense problems arising from the disposal of goods which are no longer of use to their owners. It is not easy for society to get rid of motor cars and household applicances which have outlived their useful lives, and there are limits to how the world can dispose of its growing mountains of rubbish. All such considerations challenge business operators to develop products which are easier to recycle or get rid of, or which will last much longer. Political pressures on governments will almost certainly lead to more legal constraints on business to meet these challenges.

Political Factors

Section Legal Factors highlighted the ways in which business activities can be constrained by laws in force in society, and in most cases those laws are made, amended, or repealed through the established political processes of the country in question. Political structures vary between countries, and any business manager needs to understand the working of those structures in any country where the business has operations, in securing raw materials, in production, or in marketing and distribution. In countries which have democratic structures, a business needs to be constantly alert to what changes may come about in public policies. The programs of potential alternative governments need to be scrutinized and possibly influenced through the use

of open democratic processes, so that when new laws are enacted they do not take the business by surprise and may be more helpful for the business than would otherwise have been the case.

Equally important is an understanding of the administrative processes of government through which laws and statutes are implemented. A business must be especially alert to the taxation implications of all its activities, and be ready to rearrange and retime those activities to reduce its tax liabilities. Similarly, the day-to-day administration of other departments and agencies of government may bear on the activities of a business, and it is essential for the manager to have an easy means of communication with appropriate public servants in order to sort out any problems which may crop up for the business. The best means of cooperation in this respect will vary from country to country, but one general principle is that all representations to officials must be open and never underhand nor illegal.

Technological Factors

In Section Social Factors it was noted that technological changes provide another important influence on how a business is run, introducing new products to be manufactured, new methods of manufacturing them, new means of packaging and distribution, new methods of advertising and marketing, and new means of communication to be employed in all operations. The pace of technological change appears to be accelerating all the time, and the contemporary electronic revolution in communicating information is introducing a new way of business life for all large organizations. The mobile phone, the fax, and email enable decisions to be taken and implemented instantly.

Technological changes can bring vast benefits to producers and consumers alike, but they may also pose difficult problems, particularly in the management of human resources. As old machinery becomes obsolete, staff need to be retrained to use new technology or redeployed to new activities because the new technology is not so labor-intensive. Many new machines take the place of people, so it is not unusual for established workforces to resist the introduction of new technology, and industrial relations may become fraught. Nowhere was this shown more dramatically than in the English newspaper industry in the 1980s, when decisions to introduce new technology for print-setting led to mass picketing and some violence at Wapping in east London.

At the same time, the modern revolution in electronic communications enables many more people to work at home in more conducive surroundings and avoiding the traffic congestion associated with commuting to work. Word processors, fax machines, and emails enable the workforces of many businesses to be geographically scattered, with many individuals working on a contract or consultancy basis on tasks which had previously to be done in central offices. Add to all this new technology the far-reaching potential of the Internet, and it becomes possible for more and more business to be conducted electronically, with consumers ordering, and paying for, goods on the Internet; the effectiveness of such commerce depends partly on the strength and security of computer systems, and partly on the reliability of networks used for the prompt distribution of goods.

Social Accounting

Whereas the foregoing description of the interfaces between business and society was in terms of the links between an individual business and its social context, social accounting is more concerned with macroeconomics, involving a study of how whole industries and institutions relate to the wider economy and society, and of how the production of goods and services, income formation, and income distribution relate to each other. Social accounting techniques have been widely applied in the fast developing economies of the third world, such as Iran, Malaysia, Sri Lanka, Pakistan, Indonesia, Ecuador, and Swaziland.

In the application of these techniques, Social Accounting Models, or SAMs, can be constructed for specific countries and used as integrated databases for understanding the effects of national economic policies. While the British Treasury has used Economic Models for over a quarter of a century, in most of the less developed countries similar SAMs have now been built, varying greatly according to the economic characteristics of local economic conditions. Such models may be diagrammatically represented as shown in the literature, and are increasingly used in the formation of public economic policy.

Social accounting concerns microeconomics as well, since a growing number of corporations are now active in social accounting, auditing and reporting. They publish social and environmental reports on a yearly basis, which provide detailed information about the relations with their stakeholders, such as investors, employees, consumers, suppliers, central and local governments, and environmental associations. Financial rating agencies evaluate firms not only in terms of their economic and financial performance, but also in terms of their social, ecological and ethical performance.

Abstract

This article is a historical overview of some of the influences of business upon the development of sociocultural anthropology and the consequences thereof, and a review of other major developments that shaped business anthropology over the past century. The article also discusses the most prominent areas of inquiry and practice in business anthropology that have emerged recently and how these have contributed to the current status of the subfield.

Introduction

Business anthropology is inquiry or practice in the business domain that is grounded in anthropological epistemology, methodology, or substantive knowledge. Business anthropology also may be viewed as a term of reference for the overarching field in which anthropology has forged much of its experience in the private sector. In its most general sense, business refers to the buying and selling of goods and services in the marketplace, and the organized economic activities attendant to those practices. Anthropologists have been engaged in the business domain since the early twentieth century as scholars, practitioners, and strategic consultants. From these encounters, numerous designations have emerged in anthropology: corporate, enterprise, organizational, design, finance (anthropology), and so on. The proliferation of alternative terms for the construct 'business anthropology' is a reflection of several historical currents, including tensions in the relationship between anthropology and business in the discipline, difficulties surrounding the early uses of anthropological knowledge in applied anthropology, and a lack of consensus surrounding efforts to institutionalize the study of business-related phenomena in anthropology.

The twentieth century was a turbulent period for the relationship of anthropology and business, encompassing both theoretically serious engagement through the Human Relations School and sharp criticism through Marxist and neo-Marxist studies of industry. The latter decades of the century saw more anthropologists in Europe, North America, and Asia entering into increasingly diversified relationships with businesses, including the absorption of anthropology and ethnography into the business realm and the commodification of ethnographic practice into the private sector. These developments have called for self-reflection with respect to anthropologists' engagement in business, although, for the most part, the long-term consequences have not been confronted. The present situation is one of gradual institutionalization of business anthropology in society, with hundreds of anthropologists around the globe studying about and practicing in business, and the emergence of dedicated journals and conferences (e.g., *Journal of Business Anthropology*, *International Journal of Business Anthropology*, Ethnographic Praxis in Industry Conference).

It is important not only to examine specific instances of anthropological engagement in business activity but also to explore the ways in which business has influenced anthropology. Not only is business influential in and formative of society, but as a field of study business is juxtaposed to other developments in social science that could be important to anthropology.

Anthropology and Business: Early Influences

A received view of anthropology's relationship with business often places its origins in the Hawthorne Project of the Western Electric Corporation. While these events were unprecedented in shaping a dominant paradigm for social science in US industry, it is also important to examine the role of American business in financing anthropological research in the British colonies to grasp the dynamics underlying the relationship of anthropology and business.

The idea of social anthropology (i.e., empirically grounded, theoretically relevant studies of small-scale society) initially was not provided with much support by colonial governments in Europe. To obtain financing for field research, aspiring anthropologists found it necessary to 'sell' social anthropology to colonial administrators based on its practical relevance. Such approaches were not particularly effective: colonial administrators and anthropologists competed for the same professional niches; anthropologists were disinclined to undertake practical problem-solving tasks; and there was conflict between colonial policies and anthropologists' views. It is not surprising that there were few funded chairs of social anthropology in the colonial empire, and there were no other significant sources of funding for anthropological research at the time.

Social anthropology may not have emerged in Europe at all had the Laura Spellman Rockefeller Memorial (LSRM, a branch of the Rockefeller Foundation) in the United States not set out to establish the social sciences as empirical fields that could strengthen the practical basis for social welfare. At the time, the rise of the natural sciences created pressure for a positivist approach for social science, which required funding for equipment and personnel. The financing strategy for this was devised by Beardsley Ruml, a psychology PhD from the University of Chicago who reconceptualized the social work agenda of the LSRM and distributed $21 million in grants between 1922 and 1929.

The 1920s was an era of 'welfare capitalism' in the United States, when corporations in the private sector provided

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12231-7

benefits to employees to persuade them to draw closer to a management agenda and away from unionization. This approach halted the rise of unions but was expensive to firms and was implemented on an ad hoc basis. An empirical social science could provide a more systematic basis for social welfare policies, both public and private.

Ruml's mission was politically sensitive. John Rockefeller Jr. (who oversaw the LSRM) and the parent Rockefeller Foundation (RF) had to avoid the perception of private interests directing any of the Foundation's subsidiaries. The political climate of the Progressive Era had stoked sharp criticism of the Rockefeller family by politicians and the media, particularly when the RF was used to support a study of industrial relations as a response to labor-management conflict at one of the companies controlled by the Rockefellers, after which the RF discontinued all social science research.

Thus, Ruml was careful to direct LSRM funding toward basic empirical social science research, with arms-length relationships between Rockefeller funds and the grantees. He also sought to ensure that such research led toward a positivist vision for the social sciences and social welfare aims. Ruml traveled the world, visiting institutions that met his criteria of excellence, and he met with prominent intellectuals and promising individuals. He provided block grants to outstanding institutions and allowed them to make awards to individuals. He also guided chosen individuals to institutions where funding already had been arranged.

Four major names in the history of anthropology were guided and funded by Ruml, the LSRM, and/or the RF: Bronislaw Malinowski, Elton Mayo, Alfred R. Radcliffe-Brown, and W. Lloyd Warner. In turn, these individuals influenced the relationship between anthropology and business through the Hawthorne Project, the Human Relations School, the Yankee City Series, and the intellectual ties of these programs with British social anthropology.

Perspectives on the Hawthorne Project

Ruml met the Australian psychologist Mayo early in his search for funding opportunities, and he was attracted to Mayo's ideas about industrial management and a potential role for social science. Mayo believed that labor-management relations reproduced society-wide class relationships that generated hostility within industry and a form of class warfare. He blamed management for failing to consult employees in decision making, and he saw a role for the social sciences in bringing knowledge-based guidance to the relationship. Ruml placed Mayo at the University of Pennsylvania, using Rockefeller's personal funds to support Mayo's research in industry. At Penn, Mayo began to read anthropology, and he began to send Malinowski manuscripts for comment.

Progress on Mayo's research at Penn and the strictures of that placement led Ruml to move Mayo to the Harvard Business School, where he was funded directly by the LSRM. At Harvard, Mayo began to meet corporate executives through Rockefeller's networks, including the personnel director of Western Electric Corporation, who told him about their experiments on worker fatigue at the Hawthorne Plant in Cicero, Illinois (Gillespie, 1991).

Mayo had come to realize that the Hawthorne workers were not willing to be open with him regarding their private thoughts or to share details of their lives outside the plant, which were emerging as necessary requirements in Mayo's empirical framework (Gillespie, 1991). From his reading of the literature, Mayo believed that an anthropologist might be able to access such information. The anthropologist W. Lloyd Warner came on to the scene when he was appointed as a tutor and then an assistant professor of anthropology at Harvard, and was scouting for someone to help him set up a community study in the United States where he could experiment with anthropological methods. At the same time, Mayo was interested in identifying an anthropologist who could initiate a community study in the neighborhood around Cicero, Illinois. Warner famously spent time at Hawthorne where he was involved in designing the final phase of the experiments, the Bank Wiring Observation Room (BWOR), which Warner did not carry out himself, but was conducted by Hawthorne researchers. The BWOR confirmed that workers and supervisors systematically restricted output, based upon an informal organization of the workforce (i.e., workers' spontaneous social relationships). Though Warner declined to establish his own community study in Cicero, in designing the BWOR he developed a methodology with characteristics that approximate ethnography, including the synchronized collection and analysis of observational and interview data that create an empirical record of naturalistic behavior in the workplace, thereby establishing a standard for future ethnographic studies of work (Roethlisberger and Dickson, 1939; Schwartzman, 1993).

Mayo and Warner differed sharply in their interpretations of data emerging from the BWOR. Warner and Hawthorne researchers interpreted the findings on output restriction as evidence of distrust between workers and managers based upon a dysfunctional industrial relations regime, where workers believed that if productivity increased management would cut the piece rate, so they had a disincentive to produce more per hour. Mayo rejected this view and insisted on a 'psychopathological' interpretation. According to Mayo, the 'informal organization' of the workforce could support or oppose management, and in this case, workers had developed an illogical, maladjusted perception of management that required intervention. Mayo's close relationship with Western Electric's top leadership enabled him to gain control over the Hawthorne data (which he moved to Harvard), and ultimately, his analysis of the data prevailed (Gillespie, 1991).

Human Relations School

With his interpretation of the data secure, Mayo launched a major counseling program at Hawthorne, to address industrial relations problems. This approach became the basis for the Human Relations School, which incorporated the leading works of anthropologists and psychologists to adjust labor-management relations in the name of 'scientific knowledge.' Mayo envisioned an 'administrative elite' that would carefully apply such knowledge to issues of social organization and control, echoing the interests of the RF and LSRM.

A group of anthropologists (e.g., Conrad Arensberg, Eliot Chapple, Burleigh Gardner, F.L.W. Richardson, and W. Lloyd

Warner) was sufficiently interested in the Human Relations School to warrant a launch of their own brand, with an emphasis on social structure, systems relationships, and human interactions rather than psychology (Schwartzman, 1993). When Warner moved from Harvard to the Department of Anthropology at Chicago and others joined him, this group was enabled to conduct research and consult in businesses from an anthropological perspective. The distinctive methodology employed by this group – the systematic sociology of small-scale groups, recording of behavioral interactions, and efforts to balance their focus upon workers and managers – became hallmarks of applied anthropology in industry in the United States (Partridge and Eddy, 1978) and could be traced to the intellectual tradition of British social anthropology and Warner's methodological innovations in the Yankee City Series (see below).

Adherents of the Human Relations School embraced a functionalist theory of society, in which an equilibrium state (i.e., all parts interact to support the whole) was considered normal and conflict pathological. Functionalist theory was well known and accepted in Rockefeller circles, and it was supported by industrialists such as John Rockefeller Jr., who promoted it widely. Interventions recommended to corporate managers by members of the Human Relations School were perceived by their practitioners as advancing a 'science of society' while also contributing to human welfare (i.e., promoting industrial peace and prosperity), in keeping with the goals of the LSRM. These goals were of special relevance in the years leading up to and during World War II, when industrial productivity was important to the nation's war effort.

Efforts to establish business anthropology in the United States were an integral aspect of a larger project to institutionalize applied anthropology in the United States led by pioneers of the discipline (e.g., Conrad Arensberg, Gregory Bateson, Ruth Benedict, Margaret Mead, George Murdoch, Julian Steward, and others; Partridge and Eddy, 1978). The American Anthropological Association (AAA) declined to allow this group to establish its own section within the AAA, more than hinting at the marginalization of practical anthropology on both sides of the Atlantic, and helping to explain why the American group formed the Society for Applied Anthropology (SfAA) at Harvard in 1941. The SfAA's mission was to promote 'scientific investigation' of principles underlying human relationships and to encourage the 'wide application of these principles to practical problems,' a theme that resonated with the goals of the LSRM (see for discussion Baba and Hill, 2006).

British Social Anthropology

British social anthropology was a source of theoretical and methodological rigor and innovation whose fusion of theory and ethnographic method was financed by the LSRM. Ruml was the benefactor of the London School of Economics (LSE) in the early 1920s, providing $1.25M between 1924 and 1928 (Bulmer and Bulmer, 1981; Stocking, 1995). While some of these funds benefited Malinowski and his students through the International Institute of African Languages and Cultures, the entrepreneurial Malinowski also sought funds directly from the RF. He wrote a proposal for systematic fieldwork on the tribal context of modern economic activities such as native mining, which was attuned to the RF's interests in practical applications of knowledge and addressed interventionist strategies for the colonies (Mills, 2002). Malinowski was viewed with favor by the RF, which was growing impatient with the 'lack of cooperation' from anthropologists in the United States (Goody, 1995). When the RF voted to fund Malinowski directly, his protégés at the LSE were placed in a strategic position to receive continuing support from the Colonial Social Science Research Council, which took over funding of anthropological research in the colonies after the RF wound up its support at the end of the 1930s due to the financial stress of the Great Depression (Mills, 2002).

This development provided an opportunity for Malinowski and his students to attempt to effect policy-driven economic change within the colonial context and to recognize the complexities and fraught nature of such efforts, an irony that was not lost on historians of anthropology (Stocking, 1995). After these experiences, Malinowski's enthusiasm for practical anthropology as an approach toward improvement of the colonial apparatus appears to have diminished, reinforcing the impression among some American anthropologists that practical applications in the policy realm were a risk-prone and ill-advised endeavor.

Meanwhile, Radcliffe-Brown was establishing an empirical basis for the study of kinship among the indigenous people of Australia, based on funding received from the RF through the Australian National Research Council. Radcliffe-Brown viewed society as a 'natural system,' with social structure a primary explanatory variable in relation to similarities and differences across cultures. Although the RF approved of his approach, the Australian establishment became irritated by his ersatz aristocratic and outré lifestyle and chafed at his criticism of their colonial policies. When Radcliffe-Brown tried to bypass the Australian authorities to receive funding directly from the RF near the end of his 5-year term as chair, the resulting crisis in the colony was resolved by his decision to accept an offer of employment from the University of Chicago. While at Chicago (1931–37), Radcliffe-Brown outlined his theory of structural-functionalism, and he was influential in the debate between the scientific and historical forces within anthropology, swaying a new generation away from history and toward the social sciences, the direction promoted by the RF. Significantly, however, Radcliffe-Brown did not agree with Malinowski regarding the application of anthropology to policy questions. He was a firm advocate of maintaining the primacy of theoretical questions in anthropology and leaving policy to administrators. Thus, his views were aligned with those of many academic anthropologists in the United States during the middle and late twentieth century.

The 'scientific' direction of American sociocultural anthropology strengthened by Radcliffe-Brown's structural-functionalism became a driving force within the nascent movement of applied anthropology in the United States as it gathered momentum during World War II. Adherence to science and policy as orienting frames of reference have been features that distinguish practical anthropology in America, and they suggest the intellectual foundations of its eventual association with business anthropology.

Yankee City Study

W. Lloyd Warner, Radcliffe-Brown's protégé in Australia and a former student of Malinowski at Berkeley, modernized the foundational theory and methods of British social anthropology in his own version of small-scale society research in the Yankee City Series. In this 5-year project supported by the RF, Warner and his research group developed an innovative methodology for assigning individual subjects to social classes, ranks, and statuses, and examining interactions among members of social classes within various associations (e.g., families, cliques) through interviews and ethnographic observations. This project defined the standard American social class hierarchy of lower, middle, and upper, each with a lower and upper tier (Warner and Lunt, 1941). From his complex matrix of social interaction data, Warner was able to make observations about relationships among social class and other phenomena, such as the relocation of capital outside of small towns, shifts in alliances across social classes and resentment against the wealthy, unprecedented strikes in local factories and the formation of industrial unions, and the development of support for strikers among town folk (Warner and Low, 1947).

The conceptual and methodological advances of the Yankee City Series, whose first volume was published the same year the SfAA was established (1941), grounded and legitimized applied anthropology in the United States. Ironically, the Human Relations School with which Warner was associated met its demise due to the rise of organized labor and its practices of ritualized conflict, leading to the fall of functional equilibrium theory. Critics of the Human Relations School claimed that its theory and methods failed to acknowledge unequal power relationships within corporations and upheld these relationships through manipulative interventions (Burawoy, 1979). Whether such criticism is fair is a matter of debate. Nevertheless, it is likely that this critique was a factor in the lag between the fall of this School in the 1950s and the time when business anthropology was accepted as a domain of application much later in the twentieth century.

Business Anthropology Following World War II

The academic discipline of anthropology expanded in the United States following World War II, tracing the expansion of American business into international markets. American anthropology already had shown tendencies to resist business influences, and its members' encounters with multinational corporations abroad were not always framed in mutually beneficial terms; the companies' actions sometimes threatened or harmed the well-being of peoples that anthropologists cared about (Sherry, 1983). It may have been overseas encounters that accelerated a process through which businesses were categorized as 'harm industries' even beyond the technical definition of that term (Benson and Kirsch, 2010).

Business management also tended to be cast in critical terms during mid-twentieth century, sometimes represented as proponents of schemes that would bring dire consequences to anthropological subjects (e.g., deskilling; Lamphere, 1979). A strong inflection toward Marxian theory in American anthropology after the 1960s, together with a Vietnam-era ethics code in the AAA that forbade proprietary research, created a chilly atmosphere for research or practice in/of/for businesses.

Nevertheless, several developments in the last quarter of the twentieth century brought anthropology together with business subjects in unexpected ways. A prominent impetus for change emerged from the discipline itself. One potent force was the 'crisis of representation' emerging from the critical and postmodernist movements, and the resulting diaspora of anthropologists into new venues, seeking experiences that responded to the crisis (e.g., avoidance of former colonies, entering nontraditional venues, experiments in methodology, and 'studying up'). Anthropologists learned from other fields and became hybridized, creating the institutional anthropologies (e.g., medical, legal, and educational). Some of these hybrids discovered career paths beyond the academy, finding that globally integrated forms of capitalism readily incorporate anthropological and ethnographic knowledge(s) and techniques (see Cefkin, 2009). At the same time, the discipline of anthropology became more inclusive, more involved in public interest and urgent anthropology, and less alienating of applied and practicing anthropology. Lines between academic and applied anthropology blurred as academia reached out toward partnerships with other types of institutions.

These changes have given rise to a suite of new subfields of inquiry and practice that are affiliated with the business domain, each situated somewhat differently with respect to institutions and literature, but all contributing to the knowledge of business from an anthropological perspective.

Major Areas of Inquiry and Practice

Ethnographically Informed Design

One of the first alternative field sites to emerge in the late 1970s and early 1980s as a destination for anthropologists seeking to 'study up' and experiment with new research subjects and methods was the high technology geographic center of Silicon Valley. Large corporate research venues such as Xerox's Palo Alto Research Center (PARC) provided locations where enterprising anthropologists could explore intriguing ideas such as the 'paperless office' while also observing the 'up' of management and corporate life in situ.

An early pioneer was Lucy Suchman, a graduate student in anthropology at Berkeley who drew upon Garfinkel's ethnomethodology to inspire a new approach to the study of human–computer interaction. She introduced videotaping and frame-by-frame analytic comparisons of human–human and human–machine interactions to reveal inadequacies of machine design at Xerox (Suchman, 1987). Xerox was sufficiently impressed with Suchman's work that the company changed the design of its copier machines and ultimately modified its product development process.

Suchman formed her own research group with Jeanette Blomberg, Julian Orr, and others at the Institute for Research on Learning. They became known around the world for their innovative integration of anthropology and ethnography into the product development stream of major corporations, opening up cognate areas for anthropology and ethnography in business (e.g., communities of practice, knowledge management).

In the late 1980s and 1990s, Suchman and her team collaborated with the Doblin Group of Chicago in a long-term project focused on the workplace of the future for Steelcase, known as the Workplace Project. One member of the team was Rick Robinson of Doblin, who went on to found the entrepreneurial consulting firm E-Lab (E-Lab was purchased by Sapient in 1999), a design-oriented boutique whose ethos integrated design and ethnographic methods (Squires and Byrne, 2002). The goal of the practice was to acquire nuanced, visually based, contextualized knowledge of the user's or consumer's behaviors, and to know both what the user is doing and why he or she is doing it. E-Lab introduced ethnography to the fields of product design and development, and competitors followed suit, initiating a process of hybridization between ethnography and design that has created the ethnographically informed design that may be found in corporate venues across North America, Europe, and Asia. This hybrid field grounds the Ethnographic Praxis in Industry Conference, which now incorporates many other disciplines.

Suchman's group at Xerox PARC, which initially enjoyed significant autonomy, was eventually pressured to focus on the company's priorities. When tensions between the research group and management could not be resolved to mutual satisfaction, the group elected to disband. Suchman's group at Xerox PARC was perhaps one of the most significant influences on business since the Human Relations School of the early twentieth century. On the other hand, an emphasis on ethnomethodology in design initiated at Xerox could have inadvertently exposed a vulnerability to the representation of ethnography as methodology per se, which now may be manifesting itself in the commodification of ethnography in the market.

Organizational Cultures

Management consultants did not invent the idea that organizations may resemble the cultures of societies, but they did discover that this concept was marketable if presented as a variable that their clients could influence, and they found ready markets in the West where Asian firms had unleashed competition in the last quarter of the twentieth century. Particularly appealing was the notion that organizational outcomes could be enhanced by a 'strong culture' that was consistent or integrated in its mission, goals, members' beliefs, values, and behavioral practices, and that such a culture could be achieved by an entrepreneur's intervention (Schein, 1985/1992). For example, an entrepreneur could imprint an organization with his or her values, and these might come to shape the learning experiences of a founding group and persist over time.

Academic anthropologists were challenged to respond to the idea of organizational culture in the 1980s, and it was in the technology-based firms of Silicon Valley, Route 128, and the heart of the manufacturing zone that anthropologists found an opportunity to establish authority on the subject. What emerged was a methodological and theoretical sophistication contributing to the literature on occupations and professions in complex institutions (e.g., Gregory, 1983; Dubinskas, 1988), correcting the early notion of 'strong culture' by demonstrating that organizational culture(s) in business firms may differentiate as well as integrate.

The critical and postmodern movements of the late twentieth century brought many different individual voices and points of view into anthropologists' studies of organizations (e.g., Kondo, 1990; Hamada, 1995). Fragmentation is one way to describe the perspective on organizational cultures that emerged from this period. However, it is also possible to understand this work as part of a transition toward a more nuanced view of organizations as institutional actors within larger social, economic, and technological contexts, with this phase acknowledging the agency of individuals and organizational subgroups or quasi-groups and the potency of their interests in organizations. A fuller transition to neoinstitutionalism requires not only multivocalism but also historical and regional/global contextualization of organizations, so they are no longer viewed as isolates. For example, if a founder can imprint an organization (i.e., infuse it with values beyond its technical purpose, as Selznick theorized), then one might expect to find such organizations in regions where founders' influences continue over long periods of time (e.g., in Europe, where businesses often are family-run). And it is in Europe where ethnographic studies of organizational culture remain of interest today.

The Anthropology of Consumers, Marketing, and Advertising

Intensifying economic competition among global corporations in the late twentieth century was accompanied by a need to understand diverse consumers across the regions of the world. One consequence was that Cold War-era views of consumers as rational, information-driven, and utility-maximizing beings were modified to accommodate notions of the customer as contextually embedded, emotional subjects whose lives require interpretation. With this shift, the dominant positivist standards in consumer research were adjusted to assimilate naturalistic methods such as ethnography and ethnomethodology.

An important development in anthropology that supported these changes was the acknowledgment of consumption (Miller, 1995) as the local idiom through which cultural forms express their creativity and diversity. This opened the door to more creative exchanges between anthropology and marketing. An interdisciplinary theory of consumer culture (CCT) emerged, which is a family of theoretical perspectives that define the relationships among consumer behavior, cultural meaning, and the market. Anthropologists have been central to the development of CCT. From this perspective, material goods and services are involved in the definition of the self and a coherent sense of identity, even if fragmented. Consumption is seen as integral to identity in the West, where individualism is prevalent, and much about the individual is ambiguous at birth. Consumers are not passive adopters, but culturally constituted actors who express sociocultural meanings, and act as creative agents, resisting, mutilating, and reconfiguring what they find in the market as patterns for action and reinterpretation.

These ideas were prevalent in business schools and marketing through the turn of the twenty-first century, as an alternative to the dominant scientific norm. Even so, some anthropologists were uneasy about marketing and advertising practices that might bring harm to consumers and/or harmful consequences to society over the long term. Marketing and advertising may not always be comfortable places for anthropologists, so close to the mechanisms by which consumption is produced in a capitalist society (Malefyt and Moeran, 2003).

Within the first decade of the new century, doubts began to emerge about the role of anthropology in consumer research
